[1] Typhus fever: 1 case at Savannah, Ga.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended March 17, 1928, compared with those for a like period ended March 19, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1927 and 1928, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,050,000 in 1927 and 31,657,000 in 1928. The 95 cities reporting deaths had nearly 30,370,000 estimated population in 1927 and nearly 30,961,000 in 1928. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, February 12 to March 17, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

THE FAR EAST

Report for the week ended March 3, 1928.—The following report for the week ended March 3, 1928, was transmitted by the eastern bureau of the health section of the secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Egypt —Suez.
Aden Protectorate.—Aden.
India.—Bassein, Bombay, Rangoon.
Ceylon.—Colombo.

CHOLERA

India.—Bassein, Calcutta, Madras, Rangoon.
Siam.—Bangkok.
French Indo-China.—Saigon.

SMALLPOX

Aden Protectorate.—Perim.
Iraq.—Basrah.
Ceylon. - Colombo
India.—Bombay, Calcutta, Madras, Negapatam, Rangoon.
French India.—Pondicherry.
Dutch East Indies. - Bunjermasin, Belawan-Deli, Surabaya.
China.—Shanghai, Hong Kong.
Kwantung.—Dairen
Manchuria.—Mukden.

Returns for the week ended March 3 were not received from Samarinda, Dutch East Indies, or Vladivostok, Union of Socialist Soviet Republics.

ARABIA

Aden—Plague.—According to information dated February 29, 1928, 395 cases of plague with 244 deaths have been reported to that date at Aden, Arabia. The area of prevalence is stated to have extended beyond the point of original occurrence and to have reached a village 10 miles in the interior of the country. Isolated cases had been reported in the military and European residential areas, though no European had been attacked.

CANADA

Quebec Province—Communicable diseases—Week ended March 17, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended March 17, 1928, as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	1	Scarlet fever	106
Chicken pox	64	Smallpox	22
Diphtheria	44	Tuberculosis	58
German measles	12	Typhoid fever	20
Influenza	4	Whooping cough	26
Measles	339		

Vital statistics—Quebec Province—January, 1928.—Births and deaths in the Province of Quebec for the month of January, 1928, were reported as follows:

Estimated population	2,650,000	Deaths from—Continued.	
Births	6,255	Heart disease	327
Birth rate per 1,000 population	28.3	Influenza	68
Deaths	2,859	Measles	12
Death rate per 1,000 population	12.9	Pneumonia	299
Deaths under 1 year	757	Poliomyelitis	1
Infant mortality rate	121.0	Scarlet fever	15
Deaths from—		Smallpox	0
Accidents	38	Syphilis	7
Cancer	145	Tuberculosis (pulmonary)	213
Cerebrospinal meningitis	10	Tuberculosis (other forms)	37
Diabetes	26	Typhoid fever	30
Diarrhea	109	Whooping cough	38
Diphtheria	57		

FINLAND

Communicable diseases—January, 1928.—During the month of January, 1928, communicable diseases were reported in Finland as follows:

Disease	Cases	Disease	Cases
Diphtheria	91	Paratyphoid fever	20
Dysentery	15	Poliomyelitis	1
Encephalitis lethargica	1	Scarlet fever	166
Influenza	2,923	Typhoid fever	31

Population: 3,558,220.

GREAT BRITAIN

Bristol, England—Vital statistics—1927.—During 1927, 5,023 deaths were reported at Bristol, England, the general death rate being 13.1 per thousand, as compared with a rate of 11.9 per thousand in 1926. The birth rate in 1927 was 17.0 per thousand. In 1926 it was 17.7. The infant mortality rate in 1927 was the lowest ever recorded in Bristol, 57 per thousand births.

UNION OF SOUTH AFRICA

Orange Free State—Suspect plague.—During the week ended February 11, 1928, three suspect fatal cases of plague were reported in natives in the Heilbron District, Orange Free State, Union of South Africa, on a farm.

Typhoid fever.—Under date of February 24, 1928, an outbreak of typhoid fever was reported in the native female section of the Mental Hospital, Pietermaritzburg, Natal, with 20 cases and 2 fatalities. The outbreak was attributed to a carrier among the patients.

At Vrede, Orange Free State, a mild outbreak of the disease was reported, with 36 cases in the town and native location occurring since December 24, 1927. The mild character of the epidemic was attributed to the extensive inoculation against the disease carried out two years ago on the occasion of an outbreak of typhoid fever in the same locality.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

ASST. SURG. GEN. R. C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

SUBSCRIPTION PRICE, $1.50 PER YEAR

CONTENTS

PUBLIC HEALTH REPORTS

VOL. 43 | APRIL 13, 1928 | NO. 15

EXTENT OF RURAL HEALTH SERVICE IN THE UNITED STATES, 1924–1928

By L. L. LUMSDEN, *Senior Surgeon, United States Public Health Service*

According to data obtained by the Rural Sanitation Office of the Public Health Service from the health departments of the States, the following (Table 1) is a list, by States, of counties (or districts) in which the rural sections thereof at the beginning of the calendar years 1924, 1925, 1926, 1927, and 1928, respectively, were provided with local health service under the administration of whole-time county or (local) district health officers.

TABLE 1.—*List of counties or districts in which, as of January 1, 1924, 1925, 1926, 1927, and 1928, respectively, rural sections were provided with health service under whole-time local health officers*

The accompanying map shows the location of the counties or districts in the United States in the rural sections of which local health service under the direction of whole-time local (county or district) health officers was in operation on January 1, 1928

Within the period January 1, 1927, to January 1, 1928, whole-time county or (local) district health officer service was established in 84 units and was discontinued in 7—a net gain of 77 Of the units added to the list in 1927, 64 are counties which were more or less inundated by floods in the Mississippi valley or in the eastern part of Kentucky in the spring of that year and are located as follows 18 in Arkansas, 22 in Kentucky, 16 in Louisiana, 5 in Mississippi, 2 in Missouri, and 1 in Tennessee These projects were developed under a special arrangement—the respective State health departments directly concerned, the United States Public Health Service, and the Rockefeller Foundation, together, furnishing for a stipulated period about 75 per cent of the total funds for the operation of the county health departments Whether this quota of progress in the development of whole-time county health officer service, which was precipitated by the flood conditions, is to be permanent or temporary will be

determined when and if the county governments are called upon to provide more than 25 per cent of the money for operation. In cooperative projects established under usual conditions [1] over 50 per cent of the funds for the support of the work are provided from official local sources.

Of the 414 counties or districts with local health service under whole-time local (county or district) health officers at the beginning of the present calendar year, 368, or 89 per cent, are receiving financial assistance for the support of their local health service from one or more of the following agencies: The State board of health, the United States Public Health Service, the Rockefeller Foundation, and the Children's Bureau of the United States Department of Labor.

Without assistance from outside agencies, local governments of rural communities (counties, towns, townships, or districts) in general are not disposed to appropriate adequately for the support of efficient, whole-time, local health service. Some local governments even when offered such assistance decline to appropriate their part of the budget for the service; but, according to all the evidence, development in this vitally important field of general welfare could be greatly increased by provision (which could be made at comparatively small governmental cost) to enable the State health departments and the Federal health service to offer to counties now willing to accept, and to those which would soon become willing to accept, adequate technical advice along with financial cooperation on a basis of $1 of Federal money and $3 of State money to meet four or more dollars of county money.

As health conditions in a rural community in one State influence those in other communities in that State and in other States, it seems that all the State governments and the Federal Government may be properly concerned with the development and maintenance of efficient local health service throughout our extensive rural area. The local health service, in doing its work efficiently, necessarily performs duties such as the collection of morbidity and mortality statistics and the carrying out of measures to prevent the spread of infection in intercounty and interstate traffic, for which the State governments and the Federal Government have a degree of definite responsibility.

There are in the United States about 2,500 counties or districts comparable to counties wholly or in considerable part rural to which local health service under the direction of whole-time county or local district health officers is applicable and in which such service would be highly advantageous. The number of these units of population in which such service was in operation at the beginning of the calendar years 1920, 1921, 1922, 1923, 1924, 1925, 1926, 1927, and 1928, respectively, was 109, 161, 202, 230, 250, 280, 307, 337, and 414. The

[1] Reprint No 1184, p 31, from the Public Health Reports, Oct 21, 1927.

average annual net gain in this period has been 38. At such rate of progress, about 55 years yet would be required for reasonably adequate whole-time local rural health service to be extended to all communities of the United States in which such service is needed. To augment existing factors or to bring into operation additional factors, the speeding up of production seems critically important.

Experience indicates that the best foundation for rural health service in the United States is the county health department under the direction of the qualified whole-time county health officer. It becomes more and more evident to those with practical experience in the public health field that agencies concerned with the promotion of specialized health activities, such as typhoid-fever prevention, hookworm control, tuberculosis prevention, malaria control, venereal disease prevention, or child and maternity hygiene, can perform most effectively and economically by dovetailing their specific activities in with and making them a part of a well-balanced comprehensive program of local official health service under the immediate direction of qualified whole-time local health officers.

The present budgets for the support of the health service covering the rural communities and some of the incorporated cities and towns in the counties and districts designated in the 1928 column of Table 1 total $5,685,014.33. Of the total local population of 15,508,997 receiving this service 5,418,136, or 34.94 per cent, are urban. Therefore, about $3,698,670.32 of the total investment for the local health service in these 414 projects will be expended this year for strictly rural health service.

Reasonably adequate whole-time rural health service throughout this country would cost about $20,000,000 a year. Apart from the loss in human life, human health, and human happiness, our national economic loss annually in wage earnings and in other items incident to preventable sickness because of lack of efficient county health service is estimated at over $1,000,000,000. Money invested for well-directed whole-time county health service yields to the average local tax-paying citizen an annual dividend in dollars and cents ranging under different local conditions from 100 to 3,000 per cent.

Table 2 presents, by States, the percentage of rural population having local health service under the direction of whole-time local (county or district) health officers at the beginning of 1928.

TABLE 2.—*Percentage of rural population having on January 1, 1928, local health service under whole-time local (county or district) health officers*

Over 80 per cent of our rural population is as yet unprovided with official local health service approaching adequacy. As a consequence of this deficiency, there is a sacrifice of the health and lives and the material resources of many of our people every year—a sacrifice which is needless because preventable, and preventable by measures readily within our means and demonstrated to be in the highest sense economical.

EFFECT OF SALT ON SLUDGE DIGESTION[1]

By WILLEM RUDOLFS,[2] *Chief, Department of Sewage Disposal, New Jersey Agricultural Experiment Station, New Brunswick, N. J.*

The effect of increasing amounts of sodium chloride upon the rate of organic matter decomposition in sewage sludge by bacteria is, progressively, (*a*) indifferent, (*b*) stimulating, (*c*) retarding, and (*d*) toxic. These observations, based upon a large number of laboratory experiments, are in accord with the findings of Ricket (4), Falk and Winslow (3).

[1] Paper No. 58, Department of Sewage Disposal, New Jersey Agricultural Experiment Station, New Brunswick, N. J.

[2] C. N. Henderson assisted with the necessary analyses.

There is a comparatively large number of sewage disposal plants where salt is received as mine water, brine, or soil leachings. When rather concentrated salt solutions are received continuously or temporarily a number of questions arise:

(1) How much salt can be handled by a tank without upsetting the biological equilibrium?

(2) What is its effect upon gas production?

(3) Is the composition of the gas changed?

(4) How much larger should the digestion capacity be?

METHODS AND MATERIAL

Fresh sewage solids were collected by hanging pails for 24 hours in the different sections of the flow compartments of an Imhoff tank receiving domestic waste only. The solids were thoroughly mixed and brought to the laboratory. The next day these fresh solids were mixed with ripe sludge on the basis of volatile matter content of the materials. The ratio used was 1 part of ripe sludge to 2.3 parts of fresh solids on the basis of volatile matter. The estimated time required for complete digestion of this mixture was 35 days. For the experiment, the mixed material was divided into equal portions to which varying amounts of sodium chloride were added. Table 1 shows the percentage of solids in the mixtures, the percentage of ash of these solids at the start and the end of the experiment, and the amounts of NaCl added. The mixtures were kept at laboratory temperature (averaging 70° F).

TABLE 1.—*Analyses of mixtures at beginning and end of experiment*

Sludge mixture number	NaCl added (grams per liter)	pH		Per cent solids		Per cent ash in solids	
		Begin	End	Begin	End	Begin	End
I	0	7.7	8.2	5.11	3.84	34.9	47.0
II	2	7.7	8.1	5.47	4.01	36.1	48.1
III	5	7.7	8.2	5.59	4.34	39.1	50.5
IV	10	7.7	7.9	6.03	5.40	43.7	48.9
V	20	7.8	7.4	7.17	6.35	48.2	54.9
Fresh solids		5.4		6.39		27.9	
Ripe sludge		8.2		3.88		48.5	

RESULTS

The results obtained are presented in condensed form in Table 2. The figures show that the percentage volatile matter reduction, percentage ash increase, and total gas production of mixture II receiving 2 grams of NaCl per liter of sludge, compared favorably with the mixture to which no salt was added. The effect of salt was only slightly noticeable with an addition of 5 grams, but with larger quantities, volatile matter destruction and total gas production

decreased markedly. It is interesting to note that, even with a 2 per cent salt concentration, the biological organisms retained 50 per cent of their activity as measured by the destruction of volatile matter and 25 per cent as measured by the production of gas. This, seems to be a long way from sterilization; but if the gas analyses figures are considered, it is evident that large quantities of salt affect especially those organisms responsible for methane production. The effect of the different salt concentrations is graphically shown in Figures 1 and 2, where the results are plotted on the basis of fresh

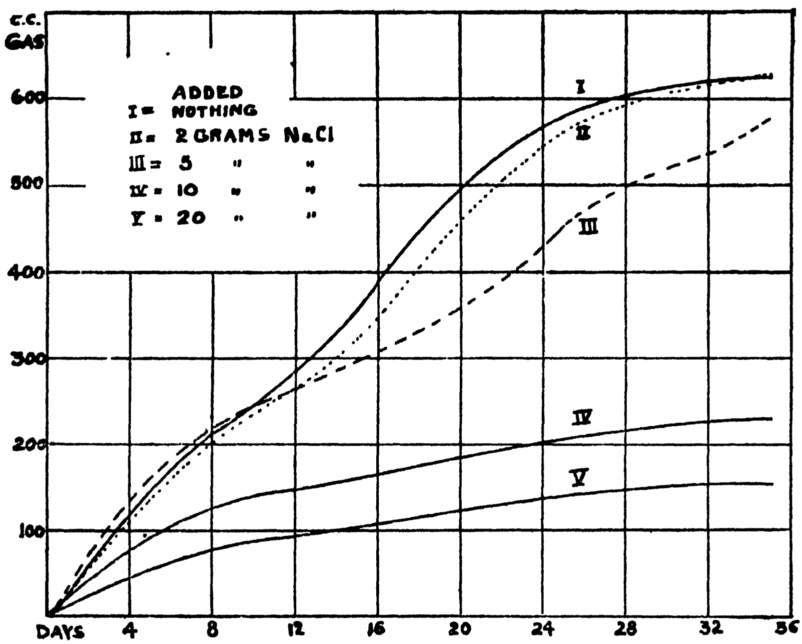

FIG. 1 Gas production per gram of volatile matter added as fresh solids from different mixtures

organic matter used. It can be seen that the percentage of volatile matter destruction in the mixture receiving 2 grams of salt was somewhat greater than it was in the untreated mixture, indicating a possible stimulation, causing greater reduction in volatile matter, but not a greater gas production. If stimulation takes place, it is in the direction of liquefaction. It is)eriod evident that a salt concentration up to 0.5 per cent has no materiai trimental effect upon the total activities of the organisms anc w ieco therefore not upset the biological balance in a digestion tank. Although the ultimate amount of gas produced from mixtures with 0.5 per cent salt concentration is nearly t cc same as from lower concentrations, the rate of gas production is ' mewhat retarded. (Fig. 1.)

[1] Analyses of accumulated gas during third part of digestion period.

With higher concentrations (1 and 2 per cent concentrations), retardation of gas production is very pronounced. Blunk (2) has found that a great reduction in gas production took place in tanks receiving salt from mine drainage. Bach (1) states that the largest quantity of chlorides recorded amounted to 3,997 p.p.m., or, in the form of NaCl, 6,570 p.p.m. Sierp (6) conducting laboratory experiments, concludes that salt solutions up to 1 per cent concentration have no influence whatsoever upon digestion activities and that with concentrations of 3 per cent salt solution only about 20 per cent reduction in decomposition takes place. The total amounts of gas produced per gram dry material (fresh solids) after 80 days was practically alike for all mixtures, except with 3 per cent salt concentrations. The ripe sludge—fresh solids mixtures used by Sierp—were on an organic-matter basis of 1: 1 (ripe sludge 47.1 per cent and fresh solids 45.4 per cent volatile matter). Such a mixture would, at average laboratory temperatures of 70° F., be completed in less than 35 days, and it is possible that after 80 days of incubation (the time employed by Sierp) the retarding effect was not noticed.

The figures given in Table 2 for the composition of the gas produced need amplification. A small quantity of methane (7.9 per cent) was produced during the first period of the digestion time (35 days' digestion time) in No. IV (with 10 grams salt), but less than 1 per cent was found in No. V (20 grams salt). Carbon dioxide production was higher at the beginning in all except No. IV. The following figures show the difference in percentages CO_2 production for the gas collected during the second and last vident that estion:

imental effo

Difference in percentages of CO_2 production during ierefore not *eriods of digestion*

ough the ultimate

xtu *nd and* cent salt con-

n lower the

	II	III	IV	V
Second period	[illegible]	5.6	8.5	28.6
Last period	[illegible]	13.7	11.2	19.8

The usual reduction in percentage CO_2 and a corresponding increase in methane production took place with the advance of digestion in mixtures I, II, and III. The low methane production of mixture IV during the second part of digestion practically stopped, with a subsequent increase in CO_2 production. With smaller quantities of salt the percentage methane was high, possibly indicating that the methane producing organisms were somewhat stimulated, but with greater amounts of salt they were retarded.

Often when NaCl is received at a plant, smaller quantities of sulphates (Ca and Mg) are mixed with it, and it is of interest to compare such a mixture of approximately the same NaCl content with one receiving salt alone. The following figures show the total gas production in cubic centimeters per gram volatile matter present and per gram volatile matter destroyed in the processes of digestion:

Total gas production in cubic centimeters per gram volatile matter present and per gram volatile matter destroyed in digestion

Experiment	Salts added (grams per liter)	Cubic centimeters of gas produced	
		Per gram volatile matter present	Per gram volatile matter destroyed
A	None	438	1,125
B	5.1 NaCl	404	1,100
C	5.25 NaCl, 1.15 gr CaSO4, and MgSO4	400	1,645

The effect of NaCl on the total gas production is slight, but indicates retardation, whereas a mixture of NaCl and sulphates appeared to be somewhat stimulating. This stimulation came mainly after a somewhat prolonged retardation of gas production. This fact is well illustrated in Figure 3, in which the daily gas production is plotted in cubic centimeters per gram of volatile matter. However, an initial stimulation took place, probably due to the NaCl, because in the mixture with NaCl alone a similar initial stimulation in gas production was apparent. In another publication (5) we have drawn attention to the fact that sulphates produce considerable H_2S, and the mixture under discussion was not an exception. The strongest odors were present during the peak of gas formation.

As the rate of digestion is not materially affected with less than one-half of 1 per cent salt concentration, no additional sludge digestion capacity is required, provided a biological balance is established and maintained. Such a balance can be secured by maintaining a correct relation between ripe sludge and fresh solids, or, in other words, by the careful addition of fresh solids and withdrawal of sludge.

SUMMARY

The effect of salt upon the rate of decomposition of sewage sludge was only slightly noticeable with additions of 5 grams per liter of sludge, but with larger quantities the destruction of volatile matter and total gas production decreased markedly. The composition of the gas changed greatly with the salt additions. With the largest

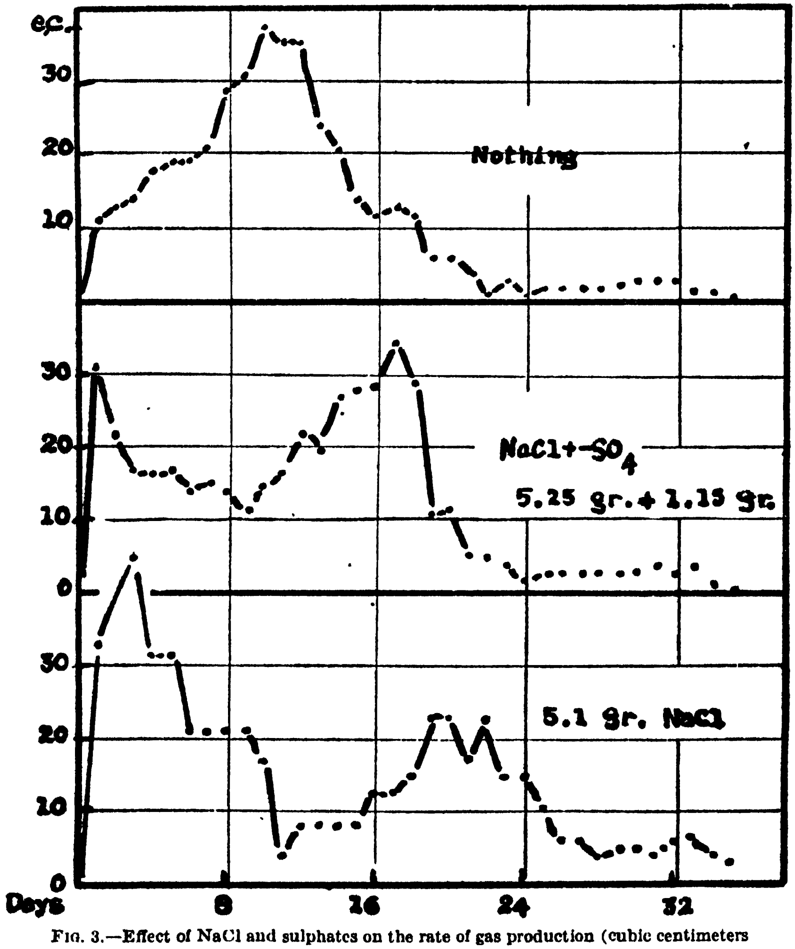

FIG. 3.—Effect of NaCl and sulphates on the rate of gas production (cubic centimeters of gas produced each day per gram of volatile matter)

quantities of salt practically no methane was produced. Mixtures of salt and sulphates appear to be somewhat stimulating.

TEST FOR PHENOLIC TASTES AND ODORS IN WATER AFTER CHLORINATION

A meeting was held in Pittsburgh, Pa., February 6, 1928, at which were present representatives of the Pennsylvania State department of health, the Ohio State department of health, the Kentucky State board of health, the Carnegie Steel Co., the Youngstown Sheet & Tube Co., the Republic Iron & Steel Co., the Jones & Laughlin Steel Corporation, the Bethlehem Steel Co., the United Gas Improvement Co., and the Koppers Co. Mr. W. L. Stevenson, chief engineer of the Pennsylvania State department of health, chairman of the meeting, appointed a committee to consider the test for phenolic tastes and odors in water after chlorination, proposed by Mr. J. W. Ellms, of Cleveland, Ohio, and report their opinion. The committee as appointed consists of F. W. Sperr, jr., director of research, the Koppers Co.; W. H. Fulweiler, chemical engineer, the United Gas Improvement Co.; F. E. Daniels, chief, industrial waste section, Pennsylvania department of health; and O. O. Malleis, chief chemist, the Koppers Co.

The committee has considered the method as presented and is of the opinion that, while in principle the method may be satisfactory for water works practice, it should be substantially modified to render it generally applicable. It is believed that, in general, a method of this sort should embody the principle of systematic dilutions with a test of each dilution, so that quantitative results can be secured. On this basis the committee has therefore drawn up a tentative method which is herewith submitted, not as final and binding, but for the purpose of inviting trial and comment. It is hoped that this method will be thoroughly examined and tried by all who are interested in the subject, and the committee would appreciate having reports of the results obtained, together with any suggestions for modification or improvement that may be considered necessary.

The tentative method proposed by the committee is as follows:

1. This test is designed as a measure of the so-called phenolic tastes and odors in water after chlorination.

2. Take 500 c. c. of the material under examination, acidulate with sulphuric acid until acid to litmus, and distill off 250 c. c. Catch the distillate in a 500 c. c. volumetric flask, make up to mark with distilled water and dilute as follows: 1 to 10; 1 to 100; 1 to 1,000, etc., preparing as many dilutions as may be necessary.

3. Take 200 c. c. of the distillate in the volumetric flask after making up to mark (this representing the original material undiluted) and a like amount of each successive dilution. Treat with a slight excess of chlorine water (a total of 0.3 p. p. m. of chlorine is usually sufficient). Let the sample stand for 15 minutes and then boil until excess of chlorine is removed as evidenced by test with orthotolidine. Make the odor test by smelling the hot liquid. Make the taste test after the liquid is cooled. In the taste test, swallowing a small quantity of the liquid is the best method for revealing the presence of taste-producing substances.

4. Results shall be expressed as the lowest dilution in which the taste and the odor are negative.

F. W. Sperr, Jr.,
W. H. Fulweiler,
F. E. Daniels,
O. O. Malleis,
Members of the Committee.

Pittsburgh, Pa., *February 27, 1928*

STUDIES ON OXIDATION REDUCTION

HYGIENIC LABORATORY BULLETIN NO. 151. STUDIES ON OXIDATION REDUCTION, PAPERS 1 10, INCLUSIVE, BY STAFF MEMBERS OF THE DIVISION OF CHEMISTRY, HYGIENIC LABORATORY, UNITED STATES PUBLIC HEALTH SERVICE

The Public Health Service has just issued a bulletin comprising 10 papers on oxidation reduction. These represent exhaustive studies upon certain fundamental principles of chemistry. They will be especially useful to chemists and to students of chemistry. The papers have already appeared separately in one form or another, but the demand for reprints has warranted the Service in collecting them under one cover.

The following list of subject headings of the different papers will give a conception of the scope of the studies collected in this bulletin:

I. Introduction. By W. Mansfield Clark.

II. An analysis of the theoretical relations between reduction potentials and pH. By W. Mansfield Clark and Barnett Cohen.

III. Electrode potentials of mixtures of 1-naphthol-2-sulphonic acid indophenol and the reduction product. By W. Mansfield Clark and Barnett Cohen.

IV. Electrode potentials of indigo sulphonates, each in equilibrium with its reduction product. By M. X. Sullivan, Barnett Cohen, and W. Mansfield Clark.

V. Electrode potentials of simple indophenols, each in equilibrium with its reduction product. By Barnett Cohen, H. D. Gibbs, and W. Mansfield Clark.

VI. A preliminary study of indophenols: (A) Dibromo substitution products of phenol indophenol; (B) substituted indophenols of the ortho type; (C) miscellaneous. By Barnett Cohen, H. D. Gibbs, and W. Mansfield Clark.

VII. A study of dichloro substitution products of phenol indophenol. By H. D. Gibbs, Barnett Cohen, and R. K. Cannan.

VIII. Methylene blue. By W. Mansfield Clark, Barnett Cohen, and H. D. Gibbs.

IX. A potentiometric and spectrophotometric study of meriquinones of the p-phenylene diamine and benzidine series. By W. Mansfield Clark, Barnett Cohen, and H. D. Gibbs.

X. Reduction potentials in cell suspensions. By R. K. Cannan, Barnett Cohen, and W. Mansfield Clark.

Copies of this bulletin may be obtained by addressing the Surgeon General, United States Public Health Service, Washington, D. C.

INTERNATIONAL SANITARY CONVENTION OF 1926 RATIFIED BY THE SENATE

On March 22, 1928, the Senate advised and consented to the ratification of the International Sanitary Convention signed at Paris on June 21, 1926.

This convention is a revision of the International Sanitary Convention of 1912, in which certain changes had become necessary because of the extension of knowledge in the field of sanitary science and a broader experience in the application of such knowledge in the field of international health. The preliminary arrangements for this revision were conducted through the International Office of Public Hygiene at Paris, which is constituted a central office for the collection and dissemination of sanitary intelligence and is empowered to cooperate with other international sanitary organizations. The convention was signed at Paris on June 21, 1926, by the plenipotentiaries of the following countries, colonies, and mandates:

Afghanistan.
Albania.
Argentine Republic.
Austria.
Belgium.
Brazil.
Bulgaria.
Chile.
China.
Colombia.
Cuba.
Czechoslovakia.
Denmark.
Dominican Republic.
Ecuador.
Egypt.
Ethiopia.
Finland.
France (including Algeria, French West Africa, French East Africa, French Indo-China, States of Syria, Grand Liban, Alaouites and Djebel-Druse, and other colonies, protectorates, possessions, and mandated territories).
Germany.
Great Britain (including Canada, Australia, New Zealand, and Union of South Africa).
Greece.
Guatemala.
Haiti.
Hedjaz.
Honduras.
Hungary.
Italy.
Japan.
Liberia.
Lithuania.
Luxemburg.
Mexico.
Monaco.
Morocco.
Netherlands.
Norway.
Paraguay.
Persia.

Union of Soviet Socialist Republics.
United States of America.
Uruguay.
Venezuela.

COURT DECISIONS RELATING TO PUBLIC HEALTH

Pneumonia held not compensable under workmen's compensation act.—(Minnesota Supreme Court; Costly *v.* City of Eveleth, 218 N. W. 126; decided February 17, 1928.) A member of a city fire department, as a result of exposure, chill, and some inhalation of smoke suffered while in the performance of his duties, contracted bronchial and lobar pneumonia from which he died. His widow was denied compensation under the workmen's compensation act by the State industrial commission, and appealed to the supreme court. Under the Minnesota compensation law mere sickness, with the exception of certain expressly enumerated occupational diseases, was not compensable unless the disease was "an accidental personal injury within the meaning" of the law. The law defined an accident as "an unexpected or unforeseen event, happening suddenly and violently, with or without human fault, and producing at the time injury to the physical structure of the body." The supreme court decided that

there had been no accident within the statutory definition, and affirmed the industrial commission's order, saying:

* * * In State ex rel. Faribault Woolen Mills Co. *v.* District Court, 138 Minn. 210, 164 N. W. 810, L. R. A. 1918F, 855, we held that typhoid fever contracted by an employee within the course of his employment and from a risk arising therefrom was not compensable. The reason was that there had been no accident within the statutory definition. The cases are reviewed and the reasons for the holding gone into at length in that decision. It is unnecessary to repeat or review them. In the present case there is no proof of "injury to the physical structure of the body" of the deceased, at the time, as a result of his work at the fire, as distinguished from the disease which soon followed. So, from the standpoint of the statutory definition of accident and its exclusionary effect upon mere sickness, we are unable to distinguish the pneumonia present in this case from the typhoid fever for which compensation was sought in the Faribault Woolen Mills Co. case.

The legislative definition of accident is admittedly difficult of application in such cases, but that difficulty does not permit us to ignore it or deny it effect. It is hard to see how it can have any function, or how we can give such obviously restrictive words their usual restrictive effect, unless we exclude from compensability such germ diseases as typhoid and pneumonia where there is no proof of a sudden and unforeseen event, as a cause, producing at the time injury to the physical structure of the body. * * *

Payment of pension to New York City Department of Health employee compelled.—(New York Supreme Court; Graef *v.* Department of Health et al., 227 N. Y. S. 82; decided January 30, 1928.) An employee of the health department of the city of New York became entitled to a pension, pursuant to city charter provisions. Beginning with January 1, 1927, the pension was denied him because the health commissioner suspected him of certain questionable activities during his employment in the department. The position the commissioner of health assumed was that, because of public policy, he had suspended the pension rights of the petitioner pending investigation. The city charter provided:

Any * * * employee who has or shall have performed duty as such * * * employee in any department of health in the city of New York, for a period of 20 years, or upward, upon his own application, in writing, * * * shall be retired from active service * * * and thereupon shall be awarded, granted, and paid from said health department pension fund by the trustees thereof, an annual sum during his lifetime not exceeding one-half the ordinary full pay of * * * [an] employee in the health department service, of the rank of the * * * employee so retired. Pensions granted under this section shall be for the natural life of the person receiving the same, and shall not be revoked, repealed, or diminished.

The employee sought to compel payment to him of the moneys withheld from him as a pension, and the court, in deciding in his favor, said that "it must be concluded that in the premises respondents are without power to order the suspension or discontinuance of the petitioner's pension, and, irrespective of how well intentioned the commissioner of health may be, the peremptory order of mandamus must be granted."

PUBLIC HEALTH ENGINEERING ABSTRACTS

The Mosquito Nuisance and Malaria (Über Muckenplage und Malaria). E. Martini. *Medizinische Klinik*, No. 12, 1927. Berlin. Germany. (Abstract by A. L. Dopmeyer.)

The author of this article published an article on the same subject in January, 1924, in which he discussed the status of malaria in Germany and the prospects for the future. His optimistic predictions as to results to be expected in the control of the mosquito nuisance and malaria were confirmed by results obtained in 1924 and 1925, but not so in 1926. This article is written to explain the reason for the large increase in numbers of mosquitoes in 1926.

The heavy rains in June and July of the previous year, which reached flood proportions in places and were responsible for the creation of a large number of pools of standing water, are characterized as being responsible for mosquitoes in larger numbers in 1926 than has been the case for a long time.

Two means of combating the mosquito are offered: (1) Winter control, by killing the mosquitoes found in houses, and (2) summer control, by killing the larvae in the breeding places. The latter method is considered the more difficult and requires personnel trained in the work, and so the winter control is suggested, although its success must be considered limited. The mosquitoes which hibernate in basements consist almost entirely of the three species: (1) *Culex pipiens;* (2) *Theobaldia annulata;* and (3) *Anopheles maculipennis.*

Winter control, however, does not take care of the *Aedes*, which lays its eggs in trenches or depressions in the earth and hatches in the spring after the first rains.

It is to be expected that after an autumn epidemic there will be a somewhat more severe epidemic in the spring of the following year, which latter begins in March, rises to a peak in May, and falls off abruptly in June. It consists of relapsing and new cases, the former being subject to immediate control, since they will be expected, but the latter probably not. These latter cases must be watched and treated so as to prevent the spread of infection.

If conditions in 1927 should again be favorable to the production of a large crop of pest mosquitoes, and meteorological conditions should be favorable to malaria production, a further increase in mosquitoes and malaria cases might result. In that event it would be wise to spare no efforts toward effective winter and summer control of mosquitoes, particularly the *Anopheles.*

Notes on the Pasteurization of Milk. J. M. Hamill. Ministry of Health. Reports on Public Health and Medical Subjects, No. 17. 14 pp. London, 1923. H. M. S. O. (Reprinted 1927). Abstract by W. G. Savage in *Bulletin of Hygiene*, vol. 3, No. 1, January, 1928, p. 17.

"A clear and concise report upon the essential factors concerned in successful Pasteurization, but one which does not go into many of the contentious scientific problems. For example, the temperature adopted for Pasteurization is taken at 145° F. to 150° F. for 30 minutes, this being regarded as a safe temperature without damage to the milk without discussing in detail the scientific evidence. (A slightly lower temperature is usually advocated in the United States.) Great stress is laid upon the absolute necessity of Pasteurizers of the 'holder' type. But little is said in regard to the mechanical difficulties in the way of the construction of a perfectly satisfactory 'holder' Pasteurizer.

" The report is intended as a brief general account of the subject and as a guide to local authorities as to requirements essential for the provision of the milk designated 'Pasteurized milk.' "

The Intermittent Irrigation Fields of Lubertzi (Moscow) During the First 10 Years of Operation (1914–1924). (In French). I. S. Bessonoff, P. S. Savos-

tianoff, and N. M. Welitchkine. 5th Report Res. Comm. No. 9, 1928. 152 pages. (Abstract by W. Rudolfs.)

The sewage of Moscow (separate system) is used for irrigating municipal lands at Lublino, which is 10 km. from Moscow, has a surface area of 948 hectares, and on which sewage is used at a rate of 56570 m³ per day; and at Lubertzi, which is 22 km. from Moscow, has an area of 640 hectares and receives sewage at the rate of 37530 m³ per day. Lutbertzi fields have been in service since 1914, and the report deals with the history of the fields during "maturation" (2-3 years), the abnormal years 1917–22, and the normal years of 1923–27. Distribution canals are constructed partly from masonry and partly from earth. The fields are divided into sections ranging from 0.25 to 2.5 hectares. The exploitation of the three farms requires 50 administrative and technical employees and 440 farmers and laborers. A stable with 150 horses and 22 cows is at the disposition of the workers. There is further a hospital, 2 schools, etc., for the nearly 2,000 persons.

The harvests are from two to two and one-half times larger than those of the surrounding prairies. Cabbage gives the best returns (33,600 kilos per hectare). Beets and hemp are also very good. The excess of green fodder is very useful for the dairy.

The effect of the treatment upon the irrigated lands is determined by chemical analyses of the sewage and drainage water collected in subterranean basins (Lysimeters). Chlorides are taken as basic figures for comparison. Suspended matter in sewage (1914) was 536 p. p. m.; fixed, 963; Cl, 147; total N, 90; NH_3, 83. During 8 years 22,000 tons of suspended matter have been placed on 450 hectares. Of the 3,099 tons of nitrogen received by the fields, 1,654 tons drained into the Pekhorka River. There were no harmful effects on the river, and it is given as an excellent example of self-purification. During 1920–21 the average results of tests of the river in p. p. m. were as follows:

	Upstream	Downstream		Upstream	Downstream
Suspended matter	5.9	4.0	NH_3	0.4	1.0
Cl	6.6	21.6	NO_3	.3	3.8
			O_2 demand	16.9	13.0

These figures give only average yearly conditions and can be used only as a summary. The authors expect to use American methods for interpretation. Three kilometers below the outfalls, the river is extensively used for recreational purposes.

Bacteriological results will be published in the following number of the reports.

Essential Features of an Efficient Municipal Sewerage System. C. A. Holmquist. *The American City*, vol. 37, No. 5, November, 1927, pp. 609–612. (Abstract by L. F. Warrick.)

The author points out, in a general discussion of municipal sewerage systems, that the essential features include (1) properly installed house plumbing, which may be regulated by plumbing code in village as well as city; (2) tight sanitary sewers laid in accordance with a comprehensive plant; (3) adequate sewage-treatment plant in charge of operators selected on the basis of knowledge and ability; (4) the tendency toward larger sewer systems, which are now made possible in New York State by the sanitary district laws; (5) the greater latitude given village trustees in sewer matters under the amended village law in the State of New York; and (6) the possibilities of sewer rentals based on water consumption as a source of revenue for building and operating sewage-treatment plants.

Some of the Newer Results Obtained at the New Jersey Experiment Station.—Willem Rudolfs. Proceedings Tenth Texas Water Works Short School, January, 1928. (Abstract by Jane H. Rider.)

Experimental work in New Jersey indicates that new methods of sewage disposal can be found only by studying the biophysicochemical conditions governing the settling, decomposition, and drying of sewage solids.

It has been found that combination of the activated sludge process and separate sludge digestion gave better results than a combination of single sedimentation and separate sludge digestion. When properly seeded, activated sludge digests more rapidly and with less odor than properly seeded solids from Imhoff or sedimentation tanks and gives a better effluent.

The addition of sea water or other liquids with high sulphate content retards the digestion of sewage solids in proportion to the amount of sulphates present. H_2S is markedly increased by even small amounts of sea water or wastes containing sulphates.

Experimental work is being done on the digestion of vegetable wastes and fine screenings Garbage from one kitchen and fine screenings were finely ground before being mixed with ripe sludge and fresh solids. Maximum gas production took place in 20 days in mixtures of ripe sludge, fresh solids, and screenings, and was similar for the limed and unlimed portions, producing more gas in 40 days than the ripe sludge-fresh solids mixture. Sufficient stability had not been reached in the 20-day period to permit the sludge to be drawn.

In mixtures of ripe sludge, fresh solids, and vegetable waste, 1:1:1 ratio, maximum gas production was completed in 40 days, the addition of lime accelerating gas production. When the fresh solids were replaced with vegetable waste, little gas was produced; lime somewhat increased its production.

The excessive lime necessary to correct the acidity in vegetable waste mixtures indicates that high gas-yielding carbonaceous substances can not be added indiscriminately to domestic sewage. If the reaction is not kept slightly alkaline, the acidity will change the type of digestion, retard the activities of certain organisms, and cause the evolution of H_2S and other volatile, odoriferous substances. Greater digestion tank capacity will be necessary if vegetable wastes are added to domestic sewage on account of the increased weight of solids and the slower rate of digestion. The separate digestion of mixed vegetable wastes is not economical

Tables and charts showing results obtained in these studies are given.

Imhoff Tanks -Their Function and Operation. A. L. Fales. Proceedings of the First Conference of Sewage Works Operators, Pennsylvania State College Bulletin, No. 1, January, 1927, pp. 10–20. (Abstract by L. F. Warrick.)

Imhoff tanks are discussed in a comprehensive manner as to function, importance of proper operation, method of putting into service, operation under both favorable and unfavorable conditions, value of records and research work, and care of plant and grounds. The function of the Imhoff tank is sedimentation of settleable suspended solids and bacterial digestion of resulting sludge in the same tank, without contaminating the settled sewage with products of sludge decomposition. Comparisons are made with plain sedimentation, septic, and separate sludge digestion tanks, in each case pointing out the advantages of Imhoff tanks operating under favorable conditions. Tried methods of overcoming various operating difficulties are briefly described and discussed.

Water Supply in Bradford (England). Lewis Mitchell. *Surveyor*, vol. 73, No. 1, 876, January 6, 1928, pp. 3 4. (Abstract by J. K. Hoskins.)

This report illustrates several divergent points of view on English and American water works practice. The city population of 288,700 consumes 58.1 gallons per capita, 35.3 gallons per capita of which are for domestic and 22.8 gallons for

industrial purposes; the corresponding consumption of outlying districts, with a population of 100,000, is 31.4 and 18.9 gallons per capita, respectively. Yet the statement is made that "although it is only one-third of the quantity consumed in 'dry' American cities, it is greatly in excess of what is reasonably required." (The word "dry" is not defined.) Metering of domestic services is not advocated, for sanitary reasons.

B. coli are present at times and are chiefly accounted for as coming from cultivated areas on the drainage area. Chlorination is not considered "expedient or desirable," and "may be considered purely as a last line of defense." Filtration is provided as a further safeguard for supplies from practically uncontaminated sources. The difficulty of finding pure sources requiring no chemical treatment is in many cases becoming acute, but Bradford has provided against this contingency.

The water is at times plumbo solvent, containing as high as 0.113 grains per gallon of lead. The acidity is neutralized by a "harmless reagent" to correct this solvent action.

Data on Applying Chlorine to Safeguard Water Systems. R. V. Donnelly. *Water Works Engineering*, vol. 81, No. 3, February 1, 1928, pp. 162–166. (Abstract by Chester Cohen.)

This article cites numerous practical points concerning the operation and care of chlorine-control apparatus. The functions of the various units of chlorinators are discussed and explained. All of the data could not well be repeated here. The following are examples of the type of information given: A solution-feed apparatus requires a water supply under at least 20 pounds per square inch pressure, and there must be 50 gallons of this water for every pound of chlorine used; the temperature of the apparatus should be kept at 45° F. or above; 50 pounds of chlorine per day can be safely drawn per cylinder; if none is drawn the cylinder tends to freeze; the usual chlorinator orifice has a ratio of 5 maximum to 1 minimum, thus an orifice of 50 pounds maximum will have a minimum of 10 pounds.

Proper care of the apparatus, protection against corrosion, flooding, stoppage, etc., are emphasized. The uses of chlorine as an algicide, as well as a bactericide, is brought out, together with present practices regarding superchlorination and dechlorination.

Colon Bacilli in Water Which May Cause Typhoid Diseases. Robb S. Spray. *Water Works Engineering*, vol. 81, No. 1, January 4, 1928, pp. 38 and 57. (Abstract by R. C. Beckett.)

The three general indices proposed for the determination of the index of pollution of water supplies, namely, fecal streptococci, proteolytic and fermentative anaerobes, and the colon bacillus group, have, due to difficulty of routine tests, been reduced to the latter group. This group, however, classifies some 34 bacteria, the most confusing being *B. aerogenes*. First indication of *B. aerogenes* is the greater amount of gas in lactose broth (60–80–90 per cent within 24 hours, as contrasted with 30–40 per cent with the true *B. coli*).

It has been impossible to devise any test which will differentiate the colon bacilli of human origin from those of lower animal origin—probably because they are the same.

Preliminary Experiments on the Treatment of Lake Michigan Water for Chicago. John R. Baylis. *Journal American Water Works Association*, vol. 17, No. 6, June, 1927, pp. 710–726. (Abstract by F. R. Shaw.)

This article gives a complete list of the studies planned at Chicago and discusses preliminary considerations in regard to clarification.

An investigation showed that it would not be economical to extend the intakes to such a distance (10 miles—40 ft. depth) from shore as would provide

a water of satisfactory clarity. The water at the present intakes has a turbidity of 3 to 100 p. p. m., averaging 10; a hardness of 130 p. p. m., mostly carbonate; appears to be saturated with soluble silica and alumina; and at times has an extremely high content of microorganisms, which presents the most difficult problem.

The author cites the desirability of designers paying more attention to "length of filter runs," and sets as a standard a yearly average of 24 hours. He says the minimum for efficient operation is 16 hours, and to secure runs in excess of 24 hours does not warrant much added expense. Reference is made to his studies at Baltimore which resulted in his suggesting a standard of clarity of 0.1 to 0.2 p. p. m. (0.5 is noticeable in bathtubs). A curve is given showing a decided break at 0.1 to 0.2 p. p. m., when the amount of coagulant was plotted against the turbidity of the filter effluent.

The laboratory at Chicago is equipped with a specially designed experimental filter which is particularly flexible, and with a stirring device which is adjustable as to depth of paddles in the sample and speed of rotation.

The experiments so far conducted indicate that the lake water is easily clarified and reacts economically to practically all the extensively used coagulants.

Experiments produced a resultant turbidity of 0.2 p. p. m., after treating with two-tenths of a grain per gallon of alum, stirring 30 minutes, and passing through the laboratory filter containing sand passing 20 mesh and retained on 30. The author believes that this should not be exceeded by more than 25 per cent in a well-designed plant. During periods when microorganisms are in abundance, more coagulant may be necessary. Treatment with iron and lime is considered. Two grains of lime (CaO) per gallon is the maximum that can be used without recarbonization, and this treatment reduces hardness 35 p. p. m.

The curve presented shows that a clarity of 0.2 p. p. m. results from a treatment of 2 g. p. g. of lime and 0.2 g. p. g. of iron with a raw water turbidity of 12 p. p. m. and 30-minute stirring.

Use of excess of lime with recarbonization is being considered, but it is initially thought to be uneconomical for a water of only 130 p. p. m. hardness. However, this treatment would solve the filter clogging troubles from microorganisms, and its sterilizing qualities might prove of value. If used, a treatment of 6 grains of lime would be desirable, with carbonization of the caustic alkalinity before passing the water through settling basins, thus reducing the total hardness to approximately 50 p. p. m.

Progress Report on Raw Water Carbon Dioxide Treatment at Lima. E. E. Smith. Sixth Annual Report of Ohio Conference on Water Purification, 1926, pp. 83-84. (Abstract by R. E. Thompson.)

Brief additional data are given on carbonization at Lima, Ohio. An improved type of coke burner has been installed. Experiments indicated that the use of artificial gas for generation of carbon dioxide would increase cost tenfold. Average amounts of chemicals used during period September, 1925–August, 1926, were as follows: Alum 2.27 g. p. g.; coke 5.9 p. p. m.; chlorine 0.25 p. p. m.—the average chemical cost per m. g. being $4.56.

DEATHS DURING WEEK ENDED MARCH 31, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended March 31, 1928, and corresponding week of 1927. (From the Weekly Health Index, April 4, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended Mar. 31, 1928	Corresponding week, 1927
Policies in force	70, 802, 855	67, 195, 853

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 101 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,650,000. The estimated population of the 95 cities reporting deaths is nearly 31,000,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended March 24, 1928, and March 26, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
43 States	1,767	1,734	
101 cities	959	1,058	917
Measles:			
42 States	19,642	15,663	
101 cities	8,030	6,615	
Poliomyelitis:			
43 States	28	10	
Scarlet fever:			
43 States	4,936	5,949	
101 cities	1,869	2,516	1,404

	1928	1927	Estimated expectancy
Cases reported—Contd.			
Smallpox:			
43 States	1,383	1,186	
101 cities	149	181	130
Typhoid fever:			
43 States	131	255	
101 cities	27	50	46
Deaths reported			
Influenza and pneumonia:			
95 cities	1,452	1,128	
Smallpox:			
95 cities	0	0	

City reports for week ended March 24, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfacory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population, July 1, 1926, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported

[1] Rabies (in man): 1 case and 1 death at Chicago, Ill.
[2] Tularaemia: 3 cases at Savannah, Ga.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended March 24, 1928, compared with those for a like period ended March 26, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1927 and 1928, respectively, authoritative figures for many of these cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,050,000 in 1927 and 31,657,000 in 1928. The 95 cities reporting deaths had nearly 30,370,000 estimated population in 1927 and nearly 30,961,000 in 1928. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, February 19 to March 24, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

THE FAR EAST

Report for the week ended March 10, 1928.—The following report for the week ended March 10, 1928, was transmitted by the Eastern Bureau of the Health Section of the Secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

Egypt.—Suez.
Aden Protectorate.—Aden.
India—Bassein, Bombay, Rangoon.
Ceylon.—Colombo.
Straits Settlements.—Singapore.
Siam.—Bangkok.

CHOLERA

India.—Bombay, Calcutta, Rangoon.
Siam.—Bangkok.
French Indo-China. Saigon, Tourane.

Iraq.—Basrah.
India.—Bombay, Calcutta, Madras, Negapatam, Rangoon, Vizagapatam.
French India Pondicherry.
French Indo-China.—Saigon.
Dutch East Indies.—Belawan-Deli, Banjermasin, Pontianak.
China.—Shanghai, Hong Kong.
Korea.—Fusan.

Returns for the week ended March 10 were not received from the following ports:

Dutch East Indies—Samarinda.
Kwantung Port Arthur, Dairen.
Towns of the South Manchurian Railway Zone.
Union of Socialist Soviet Republics. Vladivostok.

ARABIA

Aden Protectorate—Plague.—Information received under date of March 7, 1928, shows spread of the plague epidemic which has been reported present in the Aden Protectorate, Arabia, since the first week in January, 1928, with 464 cases and 294 deaths reported to March 7, 1928. It was stated that about one-fourth of the native population of Aden had fled to the interior.

CANADA

Communicable diseases—Provinces—Week ended March 17, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases in six Provinces of Canada for the week ended March 17, 1928, as follows:

Disease	Nova Scotia	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Influenza	28		1		6		35
Poliomyelitis			1				1
Smallpox			19		14	7	40
Typhoid fever		20	4			5	29

Quebec Province—Communicable diseases—Week ended March 24, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended March 24, 1928, as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	2	Scarlet fever	70
Chicken pox	22	Smallpox	40
Diphtheria	43	Tuberculosis	31
German measles	12	Typhoid fever	8
Influenza	8	Whooping cough	21
Measles	209		

Vancouver, British Columbia—Smallpox.—Smallpox in epidemic form has been reported in Vancouver, British Columbia, and its vicinity. On April 3, 1927, there were said to be 50 cases.

ECUADOR

Vital statistics—Health conditions.—Information received under date of February 18, 1928, shows the population of Ecuador, estimated as of December 31, 1925, to be about 2,000,000.

In 1925, 88,943 births were registered in Ecuador, or 44.5 per 1,000 population, and there were 15,237 deaths of infants under one year of age, the infant mortality rate being 171.3 per 1,000 births. In 1926, the death rate was 24.18 per 1,000 population in Ecuador. In Quito, with a population of about 100,000, the birth rate was 34.5 per 1,000 in 1926, and the death rate was 20 per 1,000.

The cities of Quito, Guayaquil, Ambato, Riobamba, Ibarra and Cuenca have municipal water supplies derived from springs or small streams.

Quito and Ambato are stated to have sewerage systems which are nearly completed; those of Guayaquil, Ibarra, and Latacunga are only partially constructed. In Riobamba and Cuenca sewage and surface waters are carried by open ditches through the streets.

Disease prevalence.—Prevalence of certain diseases in Ecuador is stated as follows:

Dysentery is common throughout the country.

Hookworm infection exists in the coastal region, but the index of occurrence has not been determined.

Leprosy is stated to be frequent, but, not being considered dangerous, receives little attention.

Malaria exists only in certain zones, including almost all of the coastal region.

Plague is stated to be always present at Guayaquil.

Typhoid fever is prevalent in many parts of Ecuador, especially in the interior.

Tuberculosis is said to be prevalent both in the lowlands and in the high interior of Ecuador.

GREAT BRITAIN

Scotland—Vital statistics, 1927.—The Registrar-General of Scotland has published the following statistics for Scotland for the year 1927:

	Number	Rates per 1,000 population		Number	Rates per 1,000 population
Births	96,669	19.75	Deaths—Continued.		
Illegitimate births	6,952	----	Influenza	2,026	.41
Marriages	32,589	6.66	Lethargic encephalitis	117	.02
Deaths:			Measles	660	.13
Total	65,830	13.45	Pneumonia (all forms)	5,894	1.20
Apoplexy	6,053	1.24	Puerperal sepsis	184	.04
Bronchitis	3,914	.80	Scarlet fever	200	.04
Cancer	6,918	1.41	Tuberculosis of respiratory system	3,466	.71
Cerebrospinal meningitis	138	.03	Tuberculosis (other forms)	1,401	.29
Diarrhoea and enteritis under 2 years	698	.14	Typhoid fever	41	.01
Diphtheria	485	.10	Typhus fever	2	----
Heart disease	7,900	1.61	Whooping cough	850	.17

The birth rate for the year in Scotland was 19.8 per thousand population. This is the lowest birth rate ever recorded in that country.

The infant mortality rate for the year was 89 per thousand live births. The mean of the infant mortality rates of the preceding five years was 90 per thousand births.

MADAGASCAR

Plague—December 16-31, 1927.- During the period December 16 to 31, 1927, 217 cases of plague with 184 deaths were reported in the island of Madagascar. The occurrence was distributed according to Provinces as follows: Ambositra, cases, 18, deaths, 10; Antisirabe, cases, 38, deaths, 38; Itasy, cases, 37, deaths, 30; Moramanga, cases, 8, deaths, 8; Tananarive, cases, 116, deaths, 98, of which 17 cases with 12 deaths occurred in the town of Tananarive. The distribution of occurrence according to type was: Bubonic, cases, 153, deaths, 120; pneumonic, cases, 46, deaths, 46; septicemic, cases, 18, deaths, 18.

Certain localities officially declared infected.—Information dated February 6, 1928, indicates that certain localities in the island of Madagascar have been officially declared infected and that sanitary restrictions have been ordered enforced. These localities are situated in the Provinces of Ambositra and Antisirabe. The town of Antisirabe is the sole resort and watering place in the island, having natural hot springs, government controlled.

92565°—28——4

SPAIN

Madrid—Mortality from communicable diseases—January-February, 1928.—During the months of January and February, 1928, mortality from communicable diseases was reported at Madrid, Spain, as follows:

Disease	Deaths	
	January, 1928	February, 1928
Diphtheria	2	1
Influenza	6	8
Measles	22	20
Scarlet fever	1	1
Tuberculosis	150	159
Typhoid fever	3	11

Population, 766,552.

Mortality from all causes.—The total number of deaths from all causes reported in Madrid was for January, 1928, 1,587, and for February, 1928, 1,490.

SYRIA

Beirut and the Lebanon—Smallpox—January 26-March 4, 1928.—During the period January 26 to March 4, 1928, 73 cases of smallpox were reported at Beirut, Syria, and 31 cases at other localities in the Lebanon.

UNION OF SOUTH AFRICA

Plague—Cape Province—Orange Free State—February 12-18, 1928.—During the week ended February 18, 1928, plague was reported in the Union of South Africa as follows: Cape Province—suspect case, native, in the Philipstown District; Orange Free State—three suspect cases, native, fatal, reported during week ended February 11, 1928, confirmed, and three further cases, native, with one fatality, occurring in the same locality, a farm in Heilbron District. A fatal case, native, was reported in a contact of one of the cases reported during the week ended February 11, 1928.

Typhus fever.—Fresh outbreaks of typhus fever were reported occurring in two districts of the Cape Province, in one district of Natal, and one district of Orange Free State.

During the month of January, 1928, there were reported in the Union of South Africa 50 cases of typhus fever. Of these, 48 cases with 13 deaths occurred among the native population, distributed as follows:

Cape Province, cases, 45; deaths, 13.

Natal, Orange Free State, and Transvaal, each one case. The two cases occurring in the white or European population were reported in the Cape Province.

VENEZUELA

Caracas—Communicable diseases—January, 1928.—During the month of January, 1928, mortality from communicable diseases at Caracas was reported as follows:

Disease	Deaths	Disease	Deaths
All causes	265	Diarrhea and enteritis (2 years and over)	13
Cerebrospinal meningitis	2	Tuberculosis	41
Diphtheria	2	Typhoid fever	2
Diarrhea and enteritis (under 2 years)	21		

YUGOSLAVIA

Communicable diseases—February, 1928.—During the month of February, 1928, communicable diseases were reported in Yugoslavia as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Anthrax	17	3	Poliomyelitis	1	
Cerebrospinal meningitis	6	4	Rabies	1	1
Diphtheria	208	41	Scarlet fever	1,583	235
Dysentery	25	5	Tetanus	12	6
Leprosy	1		Typhoid fever	104	31
Measles	3,406	44	Typhus fever	24	

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

ASST SURG GEN R C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

THE ACTION OF CURRENTS OF VERY HIGH FREQUENCY UPON TISSUE CELLS

A. UPON A TRANSPLANTABLE MOUSE SARCOMA.

By J. W. SCHERESCHEWSKY, *Surgeon, United States Public Health Service, Associate in Preventive Medicine and Hygiene, Harvard Medical School*

INTRODUCTION

In a previous paper [1] were reported some of the effects of an electrostatic field, forming part of a tuned circuit excited by electrical oscillations of very high frequency (135,000,000 to 8,300,000 cycles per second), upon small laboratory animals (mice). The oscillations were generated by a three-element tube oscillator of special design.

It was observed in the course of these studies that these currents, applied through the action of the field just mentioned, were capable of injuring tissues, and, moreover, that their action bore some relation to the frequency employed, oscillations of the highest and lowest frequencies studied having much less effect than those of intermediate frequencies.

Since frequency seemed an important factor in the action of these oscillations, the thought occurred that, under suitable conditions, oscillations at certain frequencies might prove more injurious to some tissue cells than to others; in other words, there might be a differential action upon tissue cells with respect to frequency

Evidently the tissue cells of transplantable tumors should be excellent experimental objects for this purpose. Here we have groups of cells distinguished from the adjacent tissue cells by their size and their active proliferation, not only contributing nothing to vital functions, but being highly detrimental to their host. Retardation of their growth or their eventual recession through the action, under suitable conditions both as to frequency and method of application, of electromagnetic radiation might well develop interesting data with respect to such possible differential action.

[1] Schereschewsky, J. W. The Physiological Effects of Currents of Very High Frequency (135,000,000 to 8,300,000 Cycles per Second) Pub Health Repts, vol 41, No 37 (Sept 10, 1926), pp 1939-1963

This paper is a preliminary report on this phase of the subject and describes attempts which have met with a certain amount of success to influence adversely the growth of a transplantable mouse sarcoma of great virulence, and also, with H. B. Andervont as collaborator, that of the well-known Rous fowl sarcoma.

The mouse tumor selected for these experiments was the strain of mouse sarcoma known as the Crocker Research Laboratory's No. 180, which was kindly furnished to the writer by Dr. F. C. Wood, director of the Crocker Laboratory for Cancer Research, for which grateful acknowledgment is hereby made.

Grateful acknowledgment is also made to Dr. M. J. Rosenau, professor of preventive medicine and hygiene of the Harvard Medical School, for permitting the use of the laboratory facilities in his department for these studies, and to Asst. Prof. Lloyd D. Felton for bacteriological work in connection with the tumors used.

This mouse sarcoma is reputed to be one of the most virulent of the known strains of laboratory tumor. Implantations yield 95 to 96 per cent of takes, and spontaneous recessions seldom occur. From information obtained on a visit to the Crocker Laboratory, in 10,000 implantations of the tumor 96 per cent were successful, while spontaneous recessions were observed in but 2 per cent of the instances.

Though the tumor is now in its twenty-third generation since it was received by the writer, no case of spontaneous recession has been observed in at least 230 control mice, the tumor causing the death of the animals in from four to six weeks from the date of implantation.

APPARATUS AND METHODS

In subjecting the tumors to the action of the very high-frequency currents, the following apparatus and methods were employed:

Generation of high-frequency currents.—For generating currents of very high frequency use was made of a three-element tube oscillator having a range of 150,000,000 to 60,000,000 cycles per second. The circuit used is one described by Huxford [2] and is excellently adapted to the efficient and stable generation of oscillations in this range of frequencies. The oscillator used in these experiments is fully described and illustrated as oscillator No. 2 in the writer's paper to which reference has already been given.

For the convenience of the reader Figure 1 shows the circuit network and Plate 1 the general appearance of the oscillator with the accompanying auxiliary circuit for applying the high-frequency currents to the tissues to be treated.

Determination of frequency.—For determining the frequency at which the oscillator was operating, the Lecher parallel wire system

[2] Huxford, W. S: Standing Waves on Parallel Wires Physical Review, Corning, N. Y., 2d series, vol. 25 (1925), pp 686–695.

described in my previous paper (to which the reader is referred) was employed. This system permits the determination of the wave length, and hence the frequency, with an accuracy of perhaps one-half of 1 per cent or less.

Utilization of oscillator output.—In studying the effects of currents of very high frequency on the growth of tumors it is obviously inexpedient to make use of any conductive arrangement, as the

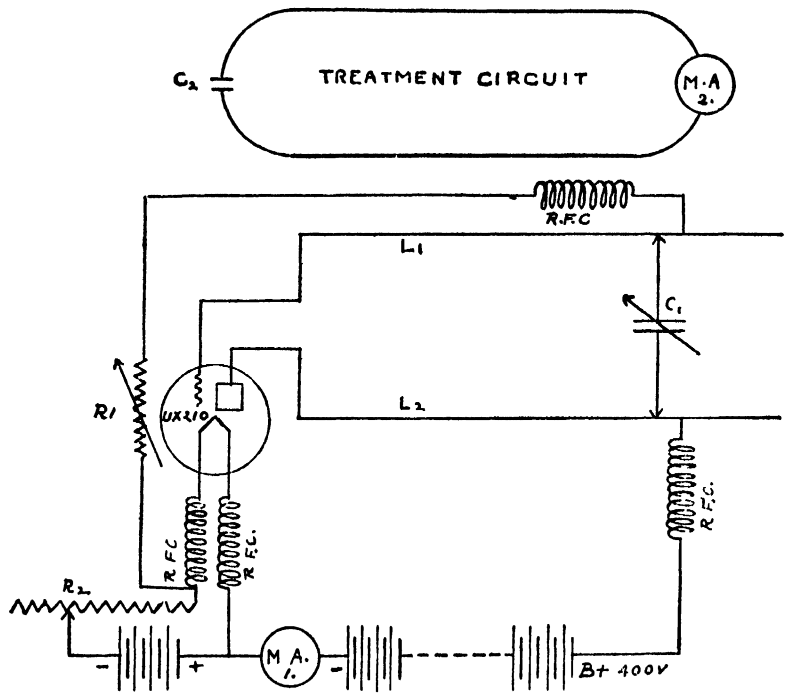

FIG 1 —Circuit diagram of high frequency oscillator (range 15,000,000 to 60,000,000 cycles)
L_1 = Grid inductance
L_2 = Plate inductance
C_1 = Tuning condenser
C_2 = Treatment electrodes
R_1 = Grid-biasing resistance (10,000 to 200,000 ohms)
R_2 = Filament rheostat
R F C. = Radio-frequency choke coils

constants of the oscillating system would, at these very high frequencies, be thereby seriously disturbed.

Therefore, the effect of these high-frequency oscillations on tumor cells was studied by means of an auxiliary tuned circuit which was inductively coupled to the oscillator. As shown by the accompanying diagram (Figure 2, and Plate I, A), this circuit consisted of an inductance and a capacity, the inductance consisting of a single-turn wire loop, having a Weston thermomilliammeter inserted at its mid-point to read the current, and the capacity of a pair of treatment electrodes,

presently to be described, which were connected through flexible leads and suitable binding posts to the inductance.

Treatment electrodes.—As in the experiments reported in the previous paper, it was the effect upon the growth of tumors of an intense electrostatic field which was investigated in the present studies. The tumors were subjected to the action of such field by including them between pairs of insulated copper plates which, through their connection by means of flexible leads, formed part of the auxiliary tuned circuit previously mentioned which was coupled inductively to the oscillator

These electrodes, of several convenient sizes (19 by 15 millimeters, 15 by 14 millimeters, and 12 by 12 millimeters) were cut out of 30-gauge copper sheet, the corners being slightly rounded. They were also bent on a slight arc of a circle, so that when applied to either side of a tumor they would tend to lift the tumor mass away from the underlying tissues, thus concentrating the influence of the electro-

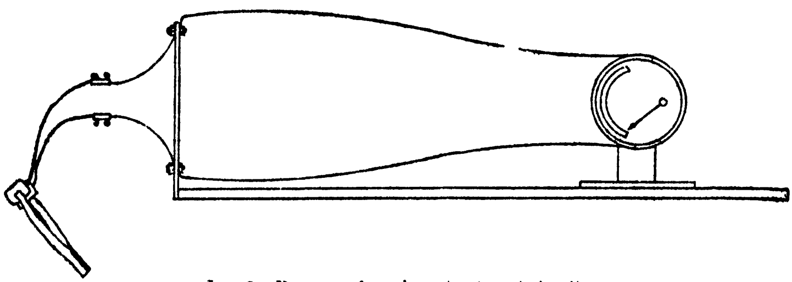

FIG 2.—Diagram of auxiliary treatment circuit

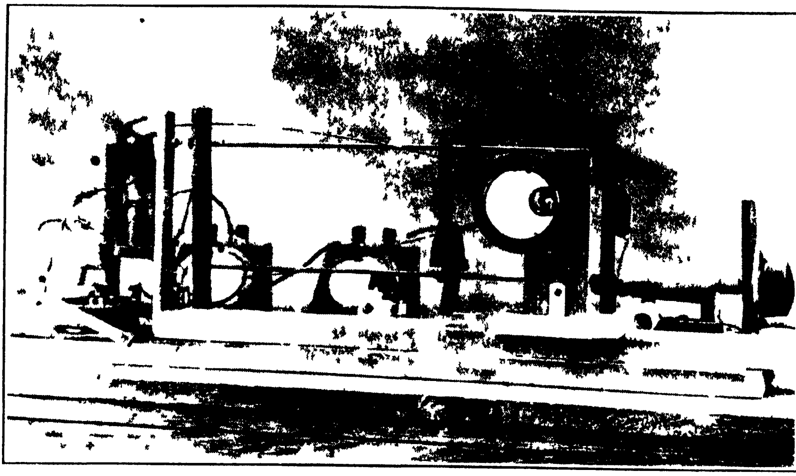
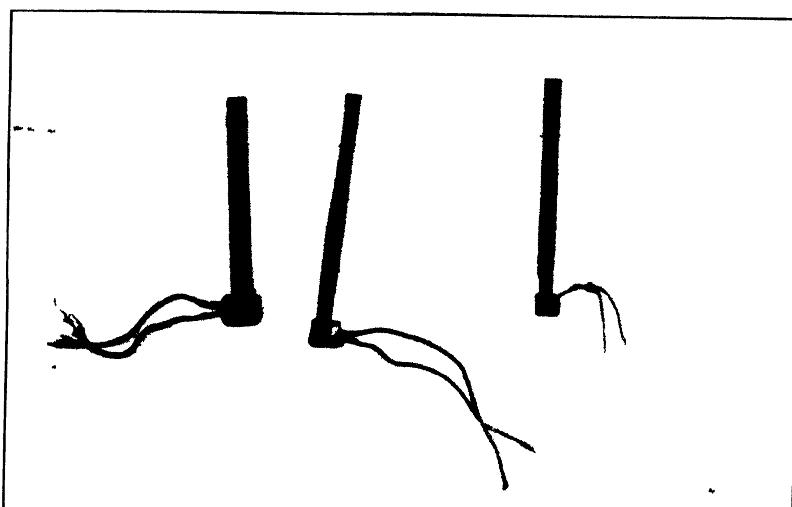
static field between the plates upon the tumor, while at the same time diminishing it upon the adjacent tissues.

In order properly to apply the treatment electrodes to the tumors, the electrodes were mounted by means of cellulose lacquer to a tissue forcepslike arrangement, made of two strips of stout celluloid about 11.5 centimeters long, 0 8 centimeters wide, and 1.5 millimeters thick. These strips were glued together at the end opposite the plates by a dab of the lacquer, and the remainder of the strips was given a suitable curve by bending them while heated. The appearance of the treatment electrodes is shown in the photograph. (Pl. I, B.)

Insulation of electrodes—Since the studies were concerned with the effects of an electrostatic field, and since the electrodes with the intervening tissues formed the capacity which, taken in conjunction with the inductance formed by their flexible leads and the rest of the wire in the auxiliary coupled circuit, caused this circuit to be tuned to the frequency generated by the oscillator, it was deemed necessary to avoid all metallic conduction effects upon the tissues subjected to treatment by carefully insulating the surfaces of the treatment electrodes.



A H[illegible]h frequency os[illegible]llator (r[illegible] e 150 000 000 t 60 000 000 [illegible]) w[illegible] [illegible] illiary treatment circuit placed [illegible]



B Treatme[illegible]t [illegible]lectro[illegible]e of var[illegible]o[illegible] [illegible]ze

As the studies proceeded the impression was strengthened that the nature and quality of the insulation covering the electrodes played an important part in the results, defective or broken-down insulation resulting in undesirable effects, such as little or no current in the auxiliary circuit, pain, sparking, local heating, burning of tissues, and the like.

After some experimenting the following insulating lacquer was found to be satisfactory:

Cellulose acetate (Eastman Kodak Co.'s No. 1097)	grams	11
Acetone, Merck's C P	cubic centimeters	100

In the preparation of this lacquer, care should be taken to avoid the presence of moisture. Before mixing, the cellulose acetate was dried by keeping it in the incubator room (which was very dry) for several days, or in a desiccator. The use of Merck's C. P. acetone was also found desirable, as the commercial variety appears to contain a small amount of moisture, resulting in milkiness of the lacquer

Before applying the lacquer, the surface of the electrodes was burnished with fine steel wool and then freed from grease by dipping in ether. This is necessary in order to secure good adhesion Each electrode was given three coats of the lacquer by dipping and allowing the surplus to drain off, each coat being first allowed to dry thoroughly. When properly applied, the insulating lacquer is glassy and transparent Air bubbles are to be avoided, as they form weak points in the insulation which are prone to break down

The insulation appears to deteriorate with use so it was scraped off and the electrodes were recoated whenever the clear glasslike appearance was lost or the insulation became loosened along the edges

Tuning of auxiliary treatment circuit —In order that any considerable oscillating current should flow through the auxiliary circuit when placed in inductive relation to the oscillator, from well-known physical considerations it is, of course, necessary that the auxiliary circuit should be approximately in resonance with the frequency at which the oscillator is operating This is readily accomplished by a "cut and try" method by varying the length of the wire forming the inductance of the auxiliary circuit until the current indicated by the thermomilliammeter inserted in the auxiliary circuit is a maximum for a given oscillator output and degree of coupling

Since practically all the studies were carried out at uniform frequencies of 68,000,000 to 66,000,000 cycles per second, once the length of the wires had been satisfactorily determined, it was not necessary to change the adjustment throughout the experiments. In this particular instance it was found that a total length of wire of 52 centimeters (including the flexible lead to the electrode) from each binding post of the meter, with a maximum spacing of 15 centimeters,

taken in conjunction with the capacity furnished by the plates of the treatment electrode, formed a circuit roughly in resonance with the frequencies mentioned above.

Using a UX 210 tube having a rating of 7.5 watts with a plate voltage of 400 and a filament current of 1.25 amperes, currents of over 500 milliamperes were readily obtainable in the auxiliary circuit. Using a more powerful tube especially adapted to short-wave transmission, such as the UX 852, with suitable plate voltage, no doubt currents of 5 or more amperes could as readily be obtained. Since the currents applied in these experiments scarcely ever exceeded 350 milliamperes, the output obtained with the UX 210 proved entirely satisfactory.

Frequencies employed.—As mentioned before, with but few exceptions, this series of experiments was conducted at frequencies, rather arbitrarily chosen, of between 68,000,000 and 66,000,000 cycles per second. In the writer's previous paper mention is made of an interesting hypothesis suggested by Prof. G. W. Pierce, of Harvard University, director of the Cruft High Tension Laboratory, that tissue cells placed in an electrostatic field and subjected to the displacement currents caused by the rapid alternations in polarity of the field may undergo some mode of electromechanical vibration which might well have definite effects upon the cell. Professor Pierce also supplied the writer with a simplified formula based on Lamb's[3] mathematical investigation of mechanical oscillations in solid elastic spheres by which the diameter of the smallest sphere capable of vibrating in some mode at a particular frequency may readily be calculated, if we assume that sound vibrations travel through tissue cells with approximately the same speed as through water.[4] Now the diameter of the tumor cells of the mouse sarcoma used in these studies varies from 12 to 15 microns. According to the formula, solid elastic spheres of such diameters should be capable of mechanical vibrations at frequencies ranging from 80,000,000 to 64,000,000 cycles per second. Lacking the means of orientation, frequencies within this range were therefore taken as a point of departure, and since these frequencies were found capable of exerting pronounced effects upon the cells of the tumor in question, experiments were continued at these frequencies until it was believed that sufficient data had been collected to justify their publication in a preliminary way.

Method of treating tumor-bearing mice.—For the sake of convenience in handling, tumors were uniformly implanted on the right anterior surface of the belly at a locality which, in human beings, would cor-

---

[3] Lamb, H.: On the Vibrations of an Elastic Sphere. Proc. London Math. Soc., Series 1, 1882, vol. 13, p. 189.

[4] For a more extended treatment of this hypothesis the reader is referred to the writer's original paper.

respond to McBurney's point. Tumors in this situation were found to grow with great rapidity, often reaching a diameter of from 4–6 millimeters in 3 days and 10–12 millimeters in 6 or 7 days.

To subject the tumor to the action of the high-frequency currents, the mouse was held in the left hand by pinching a fold of skin on the back of the neck between the thumb and forefinger while at the same time holding the tail by pressure of the middle and ring fingers against the ball of the thumb. The oscillator having been turned on and the auxiliary circuit placed in its proper inductive relation to the oscillator, the tumor was gently pinched between the insulated plates of the treatment electrodes, the current indicated by the meter in the auxiliary circuit being kept constant at the selected value by varying the filament rheostat as required.

Controls.—Ten mice out of every lot of implantations were set aside as controls, so that the course of the tumor treated could be compared with that in control mice. The dates of death of the controls were recorded as they occurred. No case of spontaneous recession of a tumor was seen in any of the controls, some 230 in number.

Effects upon the growth of tumors.—Soon after the beginning of the experiments the fact was noted that treatment in the manner described had a pronounced immediate effect upon the tumor. The mass seemed to become much smaller and softer, and a small tumor 4 or 5 millimeters in diameter, might, just after treatment, barely be palpable There was usually some local reaction within 24 hours in the shape of edema of the treated area. In favorable cases, after the edema had subsided, the remains of the tumor were represented by a mass, which grew smaller and smaller until it eventually disappeared. There was usually, too, some superficial necrosis of the skin overlying the tumor, resulting in the shedding of the hair and the formation of a small eschar which came away in 10 days to 2 weeks, leaving the skin pink and healthy beneath it. The extent to which the overlying skin was affected appears very largely to be determined by the strength of the current used and the number of treatments required to cause recession of the tumor. In cases where one treatment was sufficient and the current was kept at a relatively low value (300 milliamperes or less), the skin disturbance was slight. In all cases, however, there seemed to be some shedding of the hair, so that the treated area could be detected two or three months after the absorption of the tumor.

When properly applied—i. e., with well-insulated electrodes and current not too high—the treatment appears to cause no pain. The mice remain passive, or struggling is no greater than is observed in mice forcibly restrained for similar periods of time. If, however, the insulation has become defective, or breaks down, pain is apparently

great, as shown by squealing and struggling of the mouse. Defects in the insulation may cause severe local heating of the tissues, followed by necrosis in them, a result to be avoided by careful attention to the state of the insulation on the electrodes before their application.

Recovery naturally depends on the death of the tumor cells. This tumor appears to have such vitality that the impression was gained that if but a few viable cells were left behind, recrudescence of the tumor was bound to occur. The presence of renewed activity on the part of the tumor was, as a rule, readily detected by the increase in size and a firm elasticity in the feel, characteristic of rapidly multiplying tumor cells. Almost without exception recrudescence of the tumor, if it occurred, was manifest within a short time after treatment, as a rule within 10 days. Among the mice listed as recovered no case of recrudescence or recurrence of the tumor was observed taking place after the death of the last control mouse. For this reason, if mice survived the last control mouse tumor free and in good health, they could be regarded as recovered for practical purposes.

In Table 1 are summarized the following data in regard to 100 mice in which, as a result of treatment, the tumor receded completely and the mouse was tumor free and in good health at the date of death of the last control: Laboratory number of mouse; date of inoculation; date of first treatment; size of the tumor, in millimeters; number of treatments; frequency employed; current used, measured in milliamperes; date on which recession of the tumor was complete and the skin had returned to normal condition; date of death of the last control mouse; remarks.

[3] 1 to each.

DISCUSSION

The table sets forth the principal data with respect to 100 mice, formerly bearers of the mouse sarcoma worked with, which survived their controls tumor-free and apparently in good health.

These mice were the survivors of 403 mice which were treated and observed. Consequently the percentage of recovery was practically 25 per cent, the remaining 303 mice dying from various causes before the death of the last control mice. Certainly, these results fall far short of the ideal of 100 per cent of recoveries. However, these figures include all the mice experimented with from the very beginning, except those under treatment at the time of the present writing. As will be seen by the large gaps in the sequence of numbers of the recovered mice, results were very poor at first, but improved later on. Attention is invited to the series commencing with mouse No. 343 and ending with mouse No. 372. The only mice dying in this series were mice Nos. 352, 356, and 365, which died from some intercurrent affection after the tumor had receded. This gives 27 survivors out of a series of 30 mice, or 90 per cent of recoveries

One feature worth noting is the fact that of the 403 mice treated, only 22, or about 5.5 per cent, actually died of tumor, the remainder dying from other causes.

One circumstance which led to considerable unavoidable mortality among the mice is the association of this tumor, as is often the case, with a diphtheroid bacillus, which of itself is pathogenic for mice. This organism, a Gram positive pleomorphic diplococcus, was frequently encountered in the heart blood of mice which, after making good progress toward recovery from the tumor, began to sicken and lose weight, eventually dying in three weeks or so after treatment had been started, often after the tumor had apparently receded completely.

Asst Prof. L. D. Felton kindly isolated this organism for me from a tumor and showed not only that it might be very pathogenic for mice, but also that it had the property of causing local necrosis of tissue. Again, a number of mice were lost from intercurrent intestinal disorders so common in laboratories. Due to lack of any previous experience, the treatment, too, was responsible for the loss of a number of mice in that the dosage was too high or the treatments were unnecessarily repeated. In a delicate creature such as a mouse the treatment in itself is quite capable of causing death if the dosage is too high, and a number of mice were lost in this way, especially in the earlier days, the mice dying within 24 or 48 hours after the treatment was applied.

Even now, since histologica work has been begun on the mode of action of these high-frequency currents, the writer is of the belief

that the current values as set forth in the table are still too high, and had these been reduced to values in the neighborhood of 240 to 200 milliamperes, the results might have been materially better

Mode of action of the high-frequency currents.—At present not much positive information can be given as to the mode of action of these high-frequency currents upon the tumor cells, although histological studies, later to be reported, are now in progress which, it is hoped, will throw light on the question. The action of the electrostatic field in which the tumors are placed for treatment does not seem to be the same as that in medica diathermy with the conventional high-frequency apparatus. With low-current values (not in excess of 300 milliamperes) and the time of exposure not exceeding three or four minutes, there does not appear to be any significant heating of the tissues. If the tissues are felt immediately upon the end of treatment, the local rise in temperature of the parts is often not perceptible or is slight. Yet the diminution in size and the softening of the tumor affected immediately by the treatment is striking and often remarkable.

It is evident that a potent destructive influence is exerted upon the tumor cells which brings about their death in a large number of instances and, in favorable cases, results in the complete absorption of the cell remains.

From a preliminary study of sections made of the tumor removed immediately and 24 hours after exposure in situ for a space of three and one-half minutes at a frequency of 68,000,000 cycles per second and at current values of 300, 250, and 200 milliamperes, the impression was strong that the tumor cells, and especially their nuclei, bore the brunt of the attack, the surrounding areolar tissue being much less affected. Fragmentation of the nucleus, disappearance of cell outlines, and pyknotic nuclei of the tumor cells were some of the effects noted.

Some of these sections were kindly examined for the writer by Dr. S. B. Wolbach, professor of pathological anatomy at the Harvard Medical School. Doctor Wolbach's personal communication to the writer reads, in part, as follows:

> In general, the immediate effects of the agency you have applied to the tumor is necrosis to the tumor cells and accompanying vascular and connective tissue structures. The general picture produced is that of so-called coagulation necrosis and the most familiar corresponding picture that I know of is in completely infarcted tissues.
>
> A very striking phenomenon, however, as brought out in the slides, is the extraordinarily rapid disappearance of the necrotic tumor. I am quite unfamiliar with anything corresponding to it. In the few microscopic preparations submitted one gets the impression that there has been very rapid solution, possibly solution by autolysis (?) of the cells including the nuclei.

UPON A TRANSPLANTABLE FOWL SARCOMA

By J. W. Schereschewsky, *Surgeon, United States Public Health Service, Associate in Preventive Medicine and Hygiene, Harvard Medical School;* and H. B. Andervont, D. Sc., *Instructor in Epidemiology, Harvard School of Public Health*

Some diffidence would be felt in publishing results based on the small number of observations contained in this series were it not for the fact that, when taken in conjunction with the much greater body of material reported upon in the first section of this paper, the meagerness of the observations takes on a meaning which otherwise it would not possess.

At the time when the mouse experiments were going forward one of us (H. B. A.) was propagating, for other purposes, a strain of the Rous fowl sarcoma. The material from which this strain was started in this laboratory was derived from dried powdered tumor obtained from the Rockefeller Institute for Medical Research.

The Rous fowl sarcoma is notable because it may be propagated by injection of the cell and bacteria-free filtrate of the tumor, on account of its rapidity of growth, its tendency to extensive metastasis, its virulence, and its extreme ease of inoculation. Skin tumors are readily implanted, merely by slightly scarifying the skin and rubbing thereon a bit of fresh tumor tissue.

The following experiments were performed with tumors implanted variously in the skin, comb, and wattles of chickens. The technique and methods of subjecting these tumors to the action of the high-frequency currents were the same as those used in the experiments reported in the preceding paper.

EXPERIMENT NO. 1

White Leghorn rooster No. 226.—This fowl was inoculated November 19, 1927, with Rous fowl sarcoma, in the posterior portion of the comb.

First treatment was given November 28, 1927, when tumor in comb was about 8 millimeters in diameter.

Duration of treatment, 3 minutes at a frequency of 66,000,000 cycles and a current of 350 to 300 milliamperes.

Treatment was repeated November 29, 1927. During the second treatment the treated portion of comb became cyanotic, dried up, and 14 days later dropped off, together with the tumor. Evidently in this case the treatment was unnecessarily severe, not only destroying the tumor but the adjacent comb tissues.

On January 13, 1928, this fowl was reinoculated with tumor on the skin of the right breast. Six days later it had several well-developed skin tumors in two areas of the scarifications, each collection forming an area about 8 by 10 millimeters.

On January 19, 1928, each area was treated for 3 minutes at a frequency of 68,000,000 cycles and a current of 300 milliamperes. Immediately after treatment the tumors were much less prominent and felt soft. Superficial necrosis of the skin over the treated area became evident 3 days later, leading to scab

formation. This dropped off in 10 days, leaving the skin smooth and free from tumor on February 6, 1928. This fowl is in excellent condition and tumor free at the date of writing, March 16, 1928.

EXPERIMENT NO. 2

White Leghorn rooster No. 228.—This fowl was inoculated both in the comb and on the skin of right breast on November 19, 1927, and was noted as sick and anemic at the time of inoculation.

First treatment was on November 28, 1927, when it had a tumor mass in the comb 5 millimeters or so in diameter.

This tumor was given 3 treatments of 3 minutes each at a frequency of 66,000,000 cycles and current of 300 milliamperes on November 28, 29, and December 1, 1927, with the result that on December 6, 1927, it had completely receded. The tumor implanted in the right breast had grown slowly, so that the first treatment was not given it until December 5, 1927, when it was about 5 millimeters in diameter. The frequency was 68,000,000 cycles, the duration 3 minutes, and the current 215 milliamperes. This tumor began to recede at once, but a fresh tumor developing near by was given 3 treatments of 2 minutes each on December 8, 12, and 14, after which it, too, became inactive.

The fowl's general condition, however, characterized by grave anemia, became progressively worse, so that it died on December 26, 1927.

At the autopsy no trace of tumor nor metastasis was found.

EXPERIMENT NO. 3

Full-grown Plymouth Rock rooster No. 230.—Inoculated November 19, 1927, on the left breast.

On December 1, 1927, 3 skin tumors each 4 millimeters in diameter were each given 1½ minutes' treatment at a frequency of 68,000,000 cycles and a current of 230 milliamperes. The tumors remained quiescent until December 13, 1927, when they showed signs of renewed activity. Treatments were repeated on December 14, 24, and 31, 1927, and on January 7, 1928. On January 11, 1928, a scab 10 by 10 millimeters came away, leaving a raw, healthy area which quickly cicatrized, the fowl remaining in excellent condition until February 17, 1928.

Second inoculation.—On February 17, 1928, the fowl was reinoculated with tumor in the right breast. By February 24, 1928, a small tumor 3 millimeters in diameter had developed, which grew slowly until February 28, 1928, when it received a 3-minute treatment at a frequency of 68,000,000 cycles and a current of 220 to 200 milliamperes. This halted the growth and caused the recession of the tumor mass, which had entirely disappeared by March 6, 1928.

Third inoculation.—The fowl was inoculated for the third time on the left breast March 1, 1928. By March 10, 1928, it had developed a small tumor mass on the left breast 6 millimeters long by 4 millimeters wide. This was given a treatment on that day of 3½ minutes at a frequency of 68,000,000 cycles and a current of 250 to 200 milliamperes.

At the time of writing, March 16, 1928, there are no signs of tumor activity in the treated area. It is possible that, in this case, the fowl has gained a certain degree of immunity from the first inoculation, making the second and third crop more susceptible to the treatment.

EXPERIMENT NO. 4

Full-grown Plymouth Rock fowl No. 231.—Inoculated November 19, 1927, in the skin of the right breast.

First treatment on December 3, 1927, when 2 skin tumors, each 4 by 4 millimeters, had developed. These each were given 1½ minutes' treatment at

68,000,000 cycles and a current of 250 milliamperes, with little immediate effect. Treastment was repeated next day with a duration of 2 minutes and a current of 250 milliamperes.

This case proved obstinate and intractable new suspicious massed were observed from time to time, so that treatments were repeated on December 8, 10, 13, 14, 17, 19, 24, 27, and 29, 1927, and January 3, 1928, with a total duration of 47 minutes and current values of 280 to 220 milliamperes.

As a result of these numerous treatments a large scab was formed which, when it became detached on December 27, 1927, left a triangular raw area 23 by 15 millimeters. By December 29, 1927, this raw area had shrunk to 13.5 by 8 millimeters and was completely cicatrized by January 7, 1928. At the time of writing the scar can be detected only with difficulty.

Second inoculation.—The fowl was inoculated in the skin of the left breast on February 16, 1928. This resulted in the development on February 21, 1928, of a small tumor mass measuring 6 by 4 millimeters and consisting of several coalescent tumors. On that date treatment of 3 minutes' duration at 68,000,000 cycles and current of 250 to 220 milliamperes was given. This single treatment caused the complete recession of the tumor mass on March 6, 1928.

Third inoculation.—The fowl was inoculated for the third time on the skin of the right breast on March 1, 1928, and on March 10, 1928, the first treatment to the tumor forming a small mass 6 by 4 millimeters was given, lasting 3 minutes at the same frequency and current of 220 to 210 milliamperes. At the time of writing, these tumors are apparently receding.

EXPERIMENT NO. 5

Half-grown White Rock fowl No. 246.—Date of inoculation January 13, 1928, in right breast.

Date of first treatment January 23, 1928, when it had three tumors each 3 millimeters in diameter in a row along line of inoculation. Treatment lasted 3 minutes at a frequency of 68,000,000 cycles and a current of 250 milliamperes. As there was little immediate effect, 2 minutes' additional treatment under the same conditions was given.

There was some local edema the next day, followed by slight skin necrosis. Recession of the tumors went on continuously and was complete by February 6, 1928. This chicken is tumor-free and in good health at the present time (March 17, 1928).

EXPERIMENT NO. 6

Half-grown White Rock fowl No. 247.—Inoculated January 13, 1928, in skin of right breast. Date of first and only treatment was January 23, 1928, when there were two tumors each 3 millimeters in diameter along line of inoculation. Each tumor received a treatment, 3 minutes to one and 2 minutes to the other, at a frequency of 68,000,000 cycles and a current of 250 milliamperes. There was practically no local reaction, and the tumors receded till recovery was complete on January 27, 1928.

Second inoculation.—On March 1, 1928, the chicken which had remained tumor-free and in good health was reinoculated in the skin of the same breast. By March 9, 1928, there was a new skin tumor 4 millimeters in diameter. This was treated for 3½ minutes at the same frequency with a current of 250 to 210 milliamperes. The outcome from this treatment is still under observation, but the tumor is inactive and apparently receding.

EXPERIMENT NO. 7

Half-grown White Rock fowl No. 249.—Inoculated January 13, 1928, in the skin of the right breast.

First treatment on January 23, 1928, when it had a row of tumors 23 millimeters long and 3 to 4 millimeters wide along the inoculation scratch. This tumor formation was treated in two sections, with a duration of 3 minutes to each section, at the usual frequency and a current of 300 to 250 milliamperes. There was no further tumor activity and but trifling local reaction. Recession set in almost at once and was complete by February 4, 1928.

Second inoculation.—On March 1, 1928, this chicken received a second inoculation in the skin of the same breast. By March 10, 1928, it had developed a fresh skin tumor 7 by 6 millimeters. This was treated, on that date, for 4 minutes, at a frequency of 68,000,000 cycles and a current of 270 to 220 milliamperes, the immediate effect being great softening and diminution of the tumor. There was practically no local reaction, and at the present time of writing recession is practically complete.

From the foregoing it appears that seven chickens, of which two were Plymouth Rocks, a breed known to be especially susceptible to this tumor, were inoculated a total of fifteen times with the Rous fowl sarcoma, and in each case it was possible to induce, by the treatment which has been described, a complete recession of the tumor. So much for the bright side of the shield. On the darker side are an equal number of chickens, 1 inoculated in the comb, 1 in the wattle, and 5 in the skin of the breast, in which only retardation of the tumor growth was produced, the fowls ultimately dying from extensive tumor growth.

In at least four of these chickens the basic error was too great severity of the initial treatment. This provoked an excessive local reaction with swelling and edema which masked the multiplication of the tumor cells in the adjacent areas until the tumor had obtained such a start that treatment was ineffective.

Excluding, as being too recent, the last inoculation of fowls numbered 230, 231, 247, and 249, it appears that, out of a total of 18 inoculations there were 11 recessions and 7 deaths from tumor, or 61 per cent of recessions.

It seems, with the experience gained in the experiments both with mice and chickens, that it should be possible to better this figure. Moreover, it is also possible, in the case of the Rous fowl sarcoma, that the frequency chosen for the treatments, either the same or virtually the same as that for the mouse sarcomas, might not be the frequency at which the best results would be secured with the Rous fowl sarcoma. This is obviously a point for further investigation, in view of the considerable variation in size of the cells of this sarcoma.

CONCLUSION AND GENERAL COMMENT

From the data presented in both sections of this paper the conclusion seems justified that by exposing transplantable tumors of two strains (mouse sarcoma C. R. 180 and the Rous fowl sarcoma) to the action of an intense electrostatic field excited by high-frequency oscillations of 68,000,000 to 66,000,000 cycles per second, it is possible in a sufficient number of instances to be significant, to produce complete recession of the tumor and consequent recovery of the tumor-bearing animal.

The method, in its present state of development, has obvious limitations in that it is confined to the treatment of subcutaneous growths which can readily be included between the plates of the treatment electrodes. Within these limitations, however, the action of the electrostatic field proved highly inimical to tumor growth and development, only 22, or 5.5 per cent, of 400 mice experimented with actually dying of tumor. With mice the problem was not so much the destruction of the tumor as to preserve the mouse free from intercurrent infections until complete recession and solid recovery had taken place.

The impression was derived that mice which had undergone treatment were, for a time at least, more susceptible than normal mice to certain bacterial infections, which brought about many more deaths than did the tumors. The treatment, too, when a certain dosage was exceeded, was able of itself to cause death. Also the lack of experience as to correct dosage, proper insulation of electrodes, and similar factors was responsible for a considerable mortality which in future experiments it should be possible to avoid.

Since stable and efficient apparatus for generating these high-frequency currents has been available to the laboratorian only for about four years or so, the action of these currents on living tissues has been but little investigated. Certainly, no previous data of practical value as to physiological action were available for guidance in the experiments here reported.

Even now we are evidently only on the threshold of the possibilities for investigation. Much remains for study, particularly with respect to the changes wrought in living cells by the application, in this particular way, of these currents. Studies along these lines are now under way and will be made the subject of future report.

The hypothesis that the frequency at which these currents are produced may have the specific quality of attacking certain cells more than others is interesting and worthy of future experimentation. Observations already collected suggest that this may be the case. The first paper published on the action of those currents, to which

reference has been given, shows plainly that their action at all frequencies is not the same but that pronounced differences exist.

In a small series of experiments a much higher frequency (135,000,000 cycles per second) than the one usually employed proved to be without particular effect on the tumor cells of the mouse sarcoma, while a preliminary study of sections of treated tumors removed immediately after exposure shows that normal tissue cells surrounding the tumor seem to be less attacked by the high-frequency currents than the tumor cells themselves.

So far as the possible therapeutic application of this method and these currents to human disease is concerned, a considerable period of observation and investigation is required before one would be justified in making such attempts, although one may hope that the results of animal experimentation foreshadow, albeit though dimly at present, results which may well be of practical utility.

Finally, it may be said that the results herewith reported distinctly encourage further investigation and study. The hope is expressed, too, that others will investigate this field with its many seeming possibilities and thereby increase the likelihood of recording observations which may be susceptible of practical application

EFFECT OF CERTAIN TRADE WASTES ON SLUDGE DIGESTION [1]

By WILLEM RUDOLFS, *Chief, Department of Sewage Disposal, New Jersey Agricultural Experiment Station, New Brunswick, N J*

Little direct and reliable information concerning the influence of trade wastes upon sludge digestion is available. A thorough study of the subject will no doubt yield important results. Preliminary studies were conducted during 1927 in our laboratory, the results of which are worthy of reporting.

Fresh solids were collected in the usual manner by hanging pails in the different compartments of an Imhoff tank. The contents of the pails were mixed and brought to the laboratory. Forty-eight hours elapsed between the time of hanging the pails and that of making the initial analyses. The ripe sludge used had been kept for some time previously in the laboratory after having been drawn from the tank. The anlyses of the fresh solids and ripe sludge were as follows:

Material	Solids		pH	Alkalinity, p p m	Acidity, p p m.
	Per cent	Per cent of ash in			
Fresh solids	5 56	22 3	5 3	600	154
Ripe sludge	6 52	48 2	7 5	2,100	44

[1] Paper No. 59, Department of Sewage Disposal, New Jersey Agricultural Experiment Station, New Brunswick, N. J.

The fresh solids were mixed with ripe sludge in proportions of 1 : 1 on a dry solids basis, or of 1 : 1.28 on the basis of volatile matter. To the mixtures were added different wastes, mainly of an inorganic nature. The additions of waste material made it imperative that all mixtures be diluted with distilled water. In those cases in which laundry waste, dye waste, and H_2SO_4 were added, the amount of distilled water for diluting was smaller in proportion. On the basis of diluted mixtures the following amounts of the different materials were added per liter:

No.	Waste
1	Nothing [1]
2	Laundry, 10 per cent by volume.
3	Sulphur-black dye, 5 per cent by volume.
4	Sulphuric acid, 500 p. p. m.
5	Sulphuric acid, 1,000 p. p. m.
6	Sodium hydroxide, 500 p p m.
7	Sodium hydroxide, 1,000 p. p. m.
8	H_2SO_4, 500 p. p. m. and NaOH, 500 p. p. m.
9	$FeSO_4$, 3 gm.

[1] See analyses and description.

The laundry waste was secured from a commercial laundry and contained 500 p. p. m. chlorides, 640 p. p. m. NaOH, 81,000 p. p. m. total alkalinity.

The sulphur-black dye was liquid from a vat in which stockings had been dyed. No wash water was included and the liquid corresponded, therefore, to the material in a concentrated form received at a sewage plant. The amount added (10 per cent on the basis of fresh solids) is probably higher than is ordinarily received. The material was collected at High Point, N. C. For convenience and for the general interest the following calculations are made for that city.[3]

According to the secretary of the Chamber of Commerce at High Point, the population of the city is 30,000. Part of the city is not sewered and Mr. Weir felt that the figure should be in the vicinity of 25,000. The average flow at the outfall was about 2,250,000 gallons per day. This includes about 160,000 gallons of industrial waste from the hosiery mills. The materials used in the sulphur-black dye process are listed below with the total amounts used in all the 12 hosiery mills. These figures cover the chemicals added to the dye vats, but do not show the actual amount which goes to the sewer, because much of the dye material is obviously retained in the hosiery stock. However, the relative amounts of these various constituents in the waste as discharged are probably the same as in the fresh dye.

[3] I am indebted to Mr. Weir, assistant engineer, North Carolina State Board of Health, and to Mr. W. C. Olsen, consulting engineer, Raleigh, N. C., for some of the basic figures given here.

Material	Pounds per day
Sulphur-black dye	550
Sodium chloride	550
Sodium sulphide	550
Sodium carbonate	175

In addition to the sodium chloride shown in the tabulation, about 300 pounds are used in the various other dye processes. This must be added to the 550 pounds for a total. However, since only black-sulphur dye waste with the relative proportions of the ingredients was used in the experiment, the latter 300 pounds of sodium chloride must be left out here. As nearly as could be determined analytically (highly colored liquor) the amounts of chemicals in the waste used in the experiment were as follows:

	Per cent
Total solids	5.38
Dye	1.2
Sodium chloride	2.0
Sodium sulphide and sulphates	1.6
Sodium carbonate	0.6

The amount of dye was determined by absorption with washed-neutral-decolorizing carbon (Nuchar from the Ind. Chemical Co., New York).

About 7 per cent of the total sewage flow consisted of dye waste. On a basis of dry solids (assuming that the average amount of dry solids per capita daily is 70 grams, the amount of fresh solids received at the plant would be 1,750 kilograms. The dye waste together with the wash water has a volume of 160,000 gallons daily making a total of 405 kilograms dry additional waste, or 18.8 per cent of the total. The waste increase would require, therefore, a disposal plant with a capacity for 29,700, or, roughly 30,000, people if no detrimental effect was experienced from the waste. The amount of waste used in our experiments was three times as much as is received at High Point. The results included here are given because they show the possible effect on digestion with larger quantities.

RESULTS

The initial analyses of the mixtures in this series (No. 404) are given in Table 1.

TABLE 1.—*Initial analyses of mixtures*

No.	Mixture	Solids: Per cent	Solids: Per cent of ash in	pH
1	Ripe sludge, fresh solids	3.01	35.2	6.8
2	Ripe sludge, fresh solids, laundry waste	3.02	35.3	6.8
3	Ripe sludge, fresh solids, dye waste	3.02	35.5	7.0
4	Ripe sludge, fresh solids, H_2SO_4 (500 p. p. m.)	3.05	35.2	5.6
5	Ripe sludge, fresh solids, H_2SO_4 (1,000 p. p. m.)	3.10	35.5	5.2
6	Ripe sludge, fresh solids, NaOH (500 p. p. m.)	3.05	35.4	7.8
7	Ripe sludge, fresh solids, NaOH (1,000 p. p. m.)	3.10	35.6	8.4
8	Ripe sludge, fresh solids, H_2SO_4, NaOH (1,000 p. p. m.)	3.10	35.7	6.7
9	Ripe sludge, fresh solids, $FeSO_4$	3.14	35.7	6.5

The progress of digestion of the different mixtures was markedly different. In every case where H_2SO_4 was added, strong H_2S odors emanated from the mixtures. This was also the case with the mixture to which dye was added. Condensed notes on the odor, gas, appearance of liquid and sludge, and scum formation, after 20 and 30 days, are given in Table 2.

TABLE 2.—*Notes on consistency and odor of mixtures*

No.	After 20 days				
	Solids, top	Liquid	Odor	Sludge color	Gas
	Per cent				
1	0	Opaque	Musty	Grayish green	Much.
2	0	Yellow	do	do	Do.
3	0	Dense gray	do	do	Some.
4	50	Very dense	H_2S	Black	Much.
5	50	Black	do	Gray	Little.
6	0	Opaque	None	Gray, black	Much.
7	0	Yellow	do	do	Do.
8	0	Opaque	Ripe	Black	Do
9	0	Clear	do	do	Do.

No.	After 30 days				
	Solids, top	Liquid	Odor	Sludge	Drain ability
	Per cent				
1	0	Clear	Ripe	Black	Very good
2	0	Opaque	Tarry	do	Do
3	0	Dense	H_2S	Intense black	Fairly good
4	20	Very dense	Strong H_2S	do	Poor
5	15	do	Putreactive H_2S.	Gray	Some
6	0	Clear	Ripe	Black	Good
7	0	Opaque	Tarry	do	Very good.
8	0	Clear	H_2S	do	Do.
9	0	Very clear	Ripe	do	Do.

After 60 days, Nos. 3, 4, 5, and 8 still had strong H_2S odors, but decomposition of organic matter progressed very slowly. The H_2S odor was still perceptible in No. 3, and very strong in No. 5 after 100 days of incubation. Apparently, practically all the sulphuric acid was eventually changed partly to H_2S and partly to sulphur, which was precipitated out against the walls of the bottle, causing a thin yellow coating. Finally, this precipitated sulphur disappeared again, probably being oxidized to sulphates and combining with alkaline products formed in the course of decomposition of organic materials. The whole question, which deals with the sulphur cycle, is under further investigation at the time of this writing.

Part of the chemical results obtained are presented in Table 3, and the percentage solids reduction and ash increase, together with relative values for solids reduction, are given in Table 4. Table 4 shows that the addition of laundry waste had a slight effect on the digestion activities. The sulphur-black dye waste was particularly

detrimental, which effect was no doubt caused by some of the inorganic salts. Comparatively small quantities of H_2SO_4 did not seem to affect the digestion process at the beginning, and appeared actually to stimulate it after an incubation period of 60 days; larger quantities of H_2SO_4 appeared to be detrimental even after 60 days. A mixture of NaOH and H_2SO_4 seemed to be detrimental at the beginning, but this was reversed later. Small quantities of NaOH appeared to retard the digestion slightly, and larger quantities more. The particular quantity of iron sulphate added in the case recorded here was slightly detrimental at the beginning.

Ripe sludge	9.5	6.9	9.8	12.5		--	--	--

The effect of sulphur-black dye waste on sludge digestion was further studied in a somewhat different way. It was assumed that a city of 25,000 people would produce about 3,860 pounds of dry fresh solids daily. Assuming a removal of suspended solids of 60 per cent by settling, a plant would have to take care of 2,320 pounds of dry fresh solids daily. It was also assumed that out of 1,825 pounds dye waste used, 50 per cent would reach the sewer (900 pounds) and remain in contact with the solids for six hours before the fresh solids would be settled out.

The following experiments were then performed. To mixtures of ripe sludge and fresh solids in the ratio of 1:1 on a dry basis were

added different amounts of dye waste. The amount of dye waste was calculated to be approximately on the basis assumed above.

The following amounts were added on the basis of dry fresh solids:

No.	Fresh solids	Dye waste	No.	Fresh solids	Dye waste
	Gram	*Gram*		*Gram*	*Gram*
1	25	0	3	25	0.5
2	25	1.0	4	25	.25

The ripe sludge fresh solids used for the mixtures analyzed as follows:

Material	Solids		Volatile matter, per cent
	Per cent	Per cent of ash in	
Ripe sludge	6.90	45.1	3.80
Fresh solids	5.17	20.5	4.13

The mixtures with the different quantities of dye waste added were diluted with distilled water, shaken, and left standing for six hours, and thereafter two-thirds of the supernatant liquid was

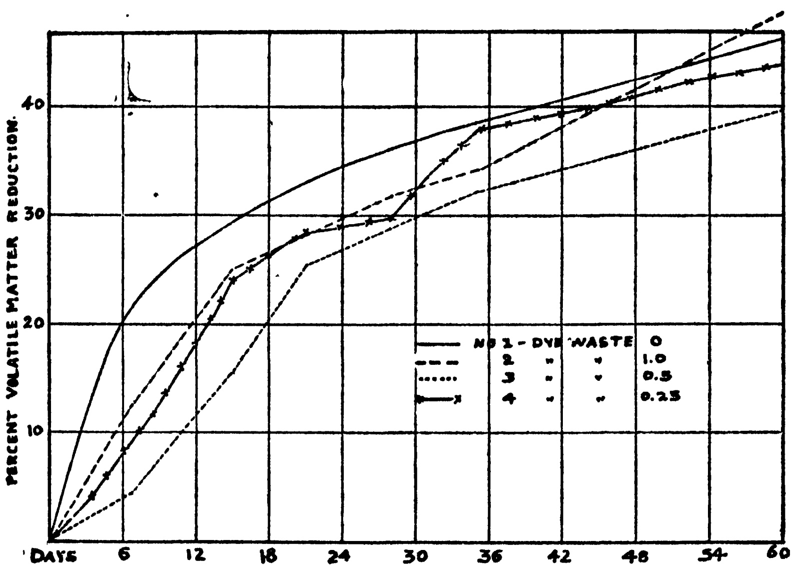

FIG. 1.—Effects of different amounts of dye waste on the percentage volatile matter reduction

siphoned off. The mixtures were then incubated at 70° F. and analyzed at intervals. The results after 35 and 60 days are given in Table 5. It can be seen that, under this procedure, the effect of the dye waste was considerably less than it was in the experiment with

larger quantities reported above. Within a week the mixtures with the dye waste produced strong H_2S odors. In 14 days this odor had disappeared from the mixture with the smallest amount of dye waste, but it took more than 5 weeks before this odor disappeared from the mixture to which the largest quantity of dye waste was added. That the dye waste had a retarding effect is clearly shown in Figure 1, where the volatile matter reduction is plotted for the entire digestion time

TABLE 5.—*Effect of dye waste on volatile matter reduction and ash increase*

No.	Beginning			35 days			60 days			Volatile matter reduction		Ash increase

SUMMARY

Preliminary studies on the effect of certain trade wastes upon the rate of sludge digestion show that with seeded material—

1. Laundry waste is somewhat detrimental to digestion activities.
2. Sulphur-black dye waste is particularly detrimental when left in contact with the sludge. It is detrimental to a much lesser extent in the digestion of fresh solids when the dye wast is partly removed with some of the supernatant liquid.
3. Comparatively small quantities of H_2SO_4 did not seem to affect digestion processes markedly during the first stages of digestion, and appeared to stimulate them somewhat after a prolonged period of incubation. Larger quantities appeared to retard
4. Small quantities of NaOH retarded activities slightly and larger quantities more.
5. A mixture of NaOH and H_2SO_4 seemed to be detrimental at the beginning, but this was reversed later
6. Certain proportions of iron sulphate have little effect on digestion.

PUBLIC HEALTH INSTITUTE AT THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY

The second Public Health Institute for health officers and other public health workers will be held at the Massachusetts Institute of Technology, Cambridge, Mass., from July 2 to 24, 1928.

This institute aims to provide for the health officers and other persons interested in health work, and opportunity to study public-

health procedures and to examine modern public-health practices under the direction of experts in their respective fields.

Practitioners of medicine frequently spend a few weeks in observation and study at great clinical centers with advantage. In this Institute of Public Health it is hoped to provide an equally valuable type of experience for health officers, public-health nurses, and other persons actively engaged or interested in public-health activities. Its main purpose is intensive instruction in the essential principles and the presentation of the best methods of modern practice in some of the important aspects of public-health work.

It is desired that application for this course be made before June 15, 1928.

Further information may be had by addressing Prof. S. C. Prescott, Department of Biology and Public Health, Massachusetts Institute of Technology, Cambridge, Mass.

COURT DECISION RELATING TO PUBLIC HEALTH

Supreme Court Interprets and Upholds Constitutionality of the Harrison Antinarcotic Act

Provision of antinarcotic act making sale, etc., of narcotic drugs unlawful except in pursuance of written order on official form construed and held constitutional.—(United States Supreme Court; Nigro *v.* United States; decided April 9, 1928.) The United States Circuit Court of Appeals for the Eighth Circuit submitted for the consideration of the United States Supreme Court four questions concerning the validity and proper construction of the Harrison Antinarcotic Act of December 17, 1914 (38 Stat. 785), as amended by the revenue act of 1918 (40 Stat. 1130). Questions I and II which were submitted read as follows:

> *Question I.*—Is the provision which is contained in the first sentence of section 2 of the act limited in its application to those persons who by section 1 are required to register and pay the tax?
>
> *Question II.*—If a broader construction is given to said provision, is the provision as so construed constitutional?

The first sentence of section 2 of the antinarcotic act provided:

> That it shall be unlawful for any person to sell, barter, exchange, or give away any of the aforesaid drugs except in pursuance of a written order of the person to whom such article is sold, bartered, exchanged, or given, on a form to be issued in blank for that purpose by the Commissioner of Internal Revenue.

The Supreme Court answered the first question in the negative and the second question in the affirmative, making it unnecessary to answer the third and fourth questions. Following are extracts from the court's opinion:

In interpreting the act, we must assume that it is a taxing measure, for otherwise it would be no law at all. If it is a mere act for the purpose of regulating and restraining the purchase of the opiate and other drugs, it is beyond the power of Congress and must be regarded as invalid, just as the child labor act of Congress was held to be, in *Bailey, Collector*, v. *Drexel Furniture Company*, 259 U. S. 20. Everything in the construction of section 2 must be regarded as directed toward the collection of the taxes imposed in section 1 and the prevention of evasion by persons subject to the tax. If the words can not be read as reasonably serving such a purpose, section 2 can not be supported.

The importation, preparation, and sale of the opiate or other like drugs and their transportation and concealment in small packages are exceedingly easy and make the levy and collection of a tax thereon correspondingly difficult. More than this, use of the drug for other than medicinal purposes leads to addiction and causes the addicts to resort to so much cunning, deceit, and concealment in the procurement and custody of the drug and to be willing to pay such high prices for it that, to be efficient, a law for taxing it needs to make thorough provision for preventing and discovering evasion of the tax—as by requiring that sales, purchases, and other transactions in the drug be so conducted and evidenced that any dealing in it where the tax has not been paid may be detected and punished and that opportunity for successful evasion may be lessened as far as may be possible.

The literal meaning of "any person," in the first line of the first sentence of section 2, includes all persons within the jurisdiction. The word "persons" is given expressly the meaning of a partnership, association, or corporation, as well as that of a natural person. Why should it not be given its ordinary comprehensive significance? The argument to the contrary in favor of limiting it to exclude all but those who are required to register and pay the tax is that it would be superfluous to include persons selling opium who are not registered because they are denounced as criminals by the first section for selling without registration. That is no reason why they may not be included under a second reasonable restriction enforceable by punishment. Of course such a restriction should be fairly adapted to obstruct the successful accomplishment of the main crime or furnish means of detecting the guilty person, and not be a fruitless, useless inhibition only resulting in what is in effect a duplication of punishment for substantially the same crime, as in the case of *United States* v. *Katz*, 271 U. S. 354, 362

It would seem to be admissible and wise in a law seeking to impose taxes for the sale of an elusive subject to require conformity to a prescribed method of sale and delivery calculated to disclose or make more difficult any escape from the tax. If this may be done, any departure from the steps enjoined may be punished, and added penalties may be fixed for successive omissions, but all for the one ultimate purpose of making it difficult to sell opium or other narcotics without registering or paying the tax.

The reasonableness of such requirements is well illustrated in the many limitations which were imposed upon the ancient freedom in the making and sale of distilled spirits to the end that the collection of the heavy tax on the subject matter might be successfully secured in spite of the temptation to avoid the tax. The provision of section 2 making it an offense to sell unless the purchaser gives a particular official form of order to the seller was enacted with a like object. The sale without such an order thus carries its illegality on its face. Its absence dispenses with the necessity of sending to examine the list of those registered to learn whether the seller is engaged in a legal sale. The requirement that the official forms can only be bought and obtained by one entitled to buy, whose name shall be stamped on the order form, and that after the sale the order form

shall be recorded, effects a kind of registration of lawful purchasers, in addition to one of lawful sellers, and keeps selling and buying on a plane where evasion of the tax will be difficult.

There are persons who may lawfully have access to or even custody of the drugs without registration. Thus included among such persons are the employees of those who have registered and paid the tax. If they were to attempt to sell such drugs the necessity for an order form from the would-be purchaser would embarrass the illegal sale, for the participants would hesitate to make a record of the transaction. Thus the operation of section 2 in preventing an individual not a registered dealer or physician from acquiring the drug other than by an order form or a prescription is directly related to tax enforcement, because such drugs are not necessarily consumed by the purchaser but may be peddled or sold illegally. These order-form provisions constitute a needed check on illegal sales and they are distinctly helpful in the detection of an attempted dealing in, or selling of, the drug free from the tax.

Section 2 of the act is the same as it was when originally passed in 1914. The construction put upon it before the amendment of section 1, by the revenue act of 1918, must be the same now as before. Under section 1 in the original act, the only provision to keep track of purchasers was the order form provision of section 2, as it is now. Without it, unless it applied to those not required to register or pay the tax, there was no restriction upon such persons whether illegal sellers or illegal purchasers in the disposition and spread of the drug, except the simple punishment for unregistered sellers in the first section, and there was entire immunity from order requirements of the purchasers from illegal sales. We can not suppose that, considering the general language of section 2, any such result was intended by Congress.

By the amendment of section 1, much higher occupation taxes were imposed and they vary in amount for producers and manufacturers and for wholesale and retail dealers and for physicians. More than that, an excise tax of one cent per ounce of the drug is imposed and payment thereof is to be evidenced by stamps attached to the bottle or box containing the drug, and the sale of the drug from anything but a stamped bottle or container is punishable. The provision for order forms is thus useful under the amended section, and there is therefore still reason for holding the provisions of section 2 to apply to all persons so as to be helpful in promoting detection of evasion from the added tax imposed under the new section 1. The two tax provisions of that section would be much less effective if a purchaser of drugs from an unregistered dealer is not required to furnish an order form. The purchaser may be himself one who should register, but has not done so, or he may be dealing in and selling the drug on which the stamp tax has not been paid and it is just as important that sales by an unregistered dealer should be punished unless made on a prescribed form as that sales by registered dealers should be subject to penalty.

* * * * * * *

Section 2 of the antinarcotic act introduces into the act the feature of the required and stamped order form to accompany each sale. It is to bear the name of the purchaser, and is addressed to the seller, with other data. Recorded as the law requires it to be, it constitutes a registry of purchasers, as distinguished from that of sellers. Congress intended not only to punish sales without registration under the first section, but also to punish them without order forms from the purchaser to the seller as a means of making it difficult for the unregistered seller to carry through his unlawful sales to those who could not get order forms. Thus an illegal unregistered seller might wish to clothe his actual unregistered sales with order forms that would give the transaction a specious appearance of legality. To punish him for this misuse of an order form is not to punish

him for not recording his own crime. It is to punish him for an added crime—that of deceiving others into the belief that the sale is a lawful sale There is no incongruity in increasing the criminal liability of the nonregistered seller who fails to use an order form in his sales, or who misuses it. Both the registered and the nonregistered seller are, under our construction of the section, punished for not using the order forms as the statute requires, or for misusing them. The order form is not a mere record of a past transaction—it is a certificate of legality of the transaction being carried on, or else it is a means of discovering the illegality and is useful for the latter purpose. * * *

We are of opinion, therefore, that the provision which is contained in the first sentence of section 2 of the act is not limited in its application to those persons who by section 1 are required to register and pay the tax. We answer the first question in the negative.

This brings us to the second question, which is "* * * is the provision as so construed, constitutional?" It was held to be constitutional in *United States* v. *Doremus,* 249 U. S. 86, 94. * * *

Four members of the Court dissented in the *Doremus case,* because of opinion that the court below had correctly held the act of Congress, in so far as it embraced the matters complained of, to be beyond its constitutional power and that the statute, in section 2, was a mere pretext as a tax measure and was in fact an attempt by Congress to exercise the police power reserved to the States and to regulate and restrict the sale and distribution of dangerous and noxious narcotic drugs. Since that time, this court has held that Congress by merely calling an act a taxing act can not make it a legitimate exercise of taxing power under section 8 of Article I of the Federal Constitution, if in fact the words of the act show clearly its real purpose is otherwise. *Child Labor Tax Case,* 259 U. S. 20, 38. By the revenue act of 1918, the antinarcotic act was amended so as to increase the taxes under section 1, making an occupation tax for a producer of narcotic drugs $24 a year, for a wholesale dealer $12, for a retail dealer, $6, and for a physician administering the narcotic, $3. The amendment also imposes an excise tax of one cent an ounce on the sale of the drug. Thus the income from the tax for the Government becomes substantial Under the narcotic act, as now amended, the tax amounts to about one million dollars a year, and since the amendment in 1919 it has benefited the Treasury to the extent of nearly nine million dollars. If there was doubt as to the character of this act as an alleged subterfuge, it has been removed by the change whereby what was a nominal tax before was made a substantial one. It is certainly a taxing act now as we held in the *Alston case.*

It may be true that the provisions of the act forbidding all but registered dealers to obtain the order forms has the incidental effect of making it more difficult for the drug to reach those who have a normal and legitimate use for it, by requirement of purchase through order forms or by physician's prescription. But this effect, due to the machinery of the act, should not render the order form provisions void as an infringement on State police power where these provisions are genuinely calculated to sustain the revenue features. The section 2 was once sustained by this court some nine years ago with more formidable reason against it than now exists under the amended statute. Its provisions have been enforced for those years. Whatever doubts may have existed respecting the order form provisions of the act have been removed by the amendment made in 1919.

* * * * * * *

In this case the qualification of the right of a resident of a State to buy and consume opium or other narcotic without restraint by the Federal Government is subject to the power of Congress to lay a tax by way of excise on its sale. Con-

gress does not exceed its power if the object is laying a tax and the interference with lawful purchasers and users of the drug is reasonably adapted to securing the payment of the tax. Nor does it render such qualification or interference with the original State right an invasion of it because it may incidentally discourage some in the harmful use of the thing taxed. *License Tax Cases*, 5 Wall. 462; *Nicol* v. *Ames*, 173 U. S. 509, 524; *Knowlton* v. *Moore*, 178 U. S. 41, 60, 61; *In re Kollock*, 165 U. S. 526, 536.

This leads to an answer to the second question in the affirmative, and makes it unnecessary for us to answer the remaining third and fourth questions.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Irrigation with Sewage Effluent. W. A. Riney. Proceedings Tenth Texas Water Works Short School, January, 1928. (Abstract by Jane H. Rider.)

Abilene, Tex., has successfully disposed of its sewage for 25 years by allowing farmers, under contract, to use the effluent from the septic tanks for broad irrigation The 400 acres of farm land available are sufficient to dispose of the 2 acre-feet per day effluent without creating a nuisance. Farms irrigated with the effluent are much more productive than adjoining land which is not irrigated. The State hospital at Abilene also successfully irrigates its farm with the effluent from its septic tank.

Climatological data obtained from the United States Weather Bureau at Abilene are given, together with a classification of the soils of Taylor County made by the United States Bureau of Soils.

The essential requirements for successfully disposing of sewage effluent by broad irrigation are (1) an ample acreage of well-drained soil in an isolated location; (2) intelligent cultivation of crops; (3) provision for storing the effluent when the land can not be irrigated.

Pont Burn Joint Sewage Disposal Works, Leadgate Co., Durham. Anon. *The Surveyor*, vol. 72, No. 1875, December 30, 1927, pp. 635–636. (Abstract by H. W. Streeter.)

The sewage disposal works, which were opened November 3, 1927, are joint between the urban district of Leadgate and the rural district of Lanchester. They were designed to treat 130,000 gallons per day, d. w. f., with allowance for 20 gallons per person daily. They consist of 2 detritus tanks, 4 sedimentation tanks, dosing chamber, storm-water tank, 3 percolating filters, and 2 humus tanks. All units except the humus tanks are placed adjoining one another. Filters are circular and dry walled, with air-lock sprinklers 73 feet in diameter. Total cost of the works was £9,600, or about $48,000.

Sludge Drying and Disposal. F. E. Daniels. Proceedings of First Conference of Sewage Works Operators, Pennsylvania State College, July 13–14, 1926. Tech. Bulletin No. 1, pp. 46 48. (Abstract by J. B Harrington.)

In this article sludge drying and disposal is described briefly. Sludge should be well rotted before draining to enable it to give up water readily and reduce odors. The percentage of water contained in various volumes of sludge is given in a table. Bad weather is often a handicap to successful sludge drying even with properly designed and constructed beds.

Three requisites for a well designed sludge bed are (1) sufficient underdrains; (2) a deep bed of properly graded material; (3) a clean surface of fine material.

Operation of Milwaukee Sewage Treatment Plant. Robert Cramer and John Arthur Wilson. *Public Works*, vol. 59, No. 1, January, 1928, pp. 20–23. (Abstract by R. J. Faust.)

This article outlines the treatment equipment available, the operating results, operating difficulties, operating cost, and future improvements at the Milwaukee activated sewage treatment plant.

The purification, judged by removal of suspended solids, bacteria count, or oxygen demand, is practically perfect. Operating difficulties arose from some inadequate equipment, lack of skill in operation, and an inadequate operating force. Organization of operating force, cost of repairs, and coal have added greatly to the past operating cost. Studies with experimental treatment plants prove that the city's sewage can be treated at three times the rate in gallons per cubic foot of air, as compared with the main plant, and have produced a sludge that can be successfully filtered, giving rise to the hope that a considerable saving can be accomplished in the future.

Odor Nuisances at Sewage Works—The Use of Chlorine. L. H. Enslow. *The Surveyor*, vol. 73, No. 1880, February 3, 1928, pp. 183 184. (Abstract by H. W. Streeter.)

Emanating from sewers and sewage plants are several different odors. Hydrogen sulphide has been shown to be the most serious of the odor-producing gases and is also destructive to masonry structures.

In odor control, prevention rather than destruction is a chief objective. The introduction of chlorine at a point where sewage is fresh is important, though frequently the sewage becomes stale before a major portion of it can be collected for treatment.

Where odor production exists, the following conditions seemingly must occur simultaneously: (1) Presence of sulphates, (2) hydrogen sulphide-producing bacteria, (3) temperature sufficiently high to promote rapid growth of sulphide-splitting organisms, and (4) period of time necessary for producing hydrogen sulphide Elimination of but one of these factors will result in securing effective control of hydrogen-sulphide generation. Odor destruction consists primarily in splitting up the hydrogen sulphide in sewage

Another factor in odor control is the effect of the course of the sewage, whereby an intimate mixture may be caused between fresh sewage and liquid heavily laden with hydrogen sulphide. Saving in chlorine consumption may be effected by changes in flow chambers to prevent disturbance of the lower 5 feet of liquid in the chamber. Chlorine application to the influent will effect complete odor elimination at moderate expense. On the whole, odor control is much more readily effected at separate sludge digestion plants.

In conclusion, examples are given of chlorination for odor control at Neodesha and Independence, Kans.

Developments in Sewage Treatment. G. G. Nasmith. *The Surveyor*, vol. 73, No. 1880, February 3, 1928, pp. 179 180. (Abstract by H. W. Streeter)

This article is a review of progress in sewage treatment during the year 1927, under the headings: Activated sludge process, colloiders, fine screens, removal of oil, sludge digestion and treatment, storm-water tanks, sewage chlorination, sewage-treatment mechanisms, and pollution of water supplies.

The author notes that although no great discoveries were made during the year, a steady accumulation of new knowledge and confirmation of earlier observations have taken place, together with the establishment of numerous chemical, physical, and biological facts. He notes especially the results of chlorination of raw **sewage in respect to prevention of Imhoff tank foaming and of excessive film formation on trickling filters, and the improvements in sludge digestion effected by pH adjustment, by daily addition of small amounts (not over 2 per cent) of fresh solids and by temperature adjustment to an optimum of 80° F.**

The difficulties involved in the operation of the activated sludge method and the means of overcoming them are discussed in detail; likewise those entailed in

the digestion of sludge. The increasing attention being devoted to stream pollution and to the creation of river boards is emphasized.

Spent Gas Liquor in Relation to Sewage Disposal. H. Ross Hooper, *The Surveyor*, vol. 73, No. 1879, January 27, 1928, pp. 111–112. (Abstract by H. W. Streeter.)

Spent gas liquor is dangerous to fish life and cattle and detrimental to small streams, as its oxygen-absorbing qualities prevent and retard self-purification. The difficulties of dealing with gas liquor have become more acute because of (*a*) the increased manufacture of gas for domestic uses; (*b*) the introduction of vertical retorts with use of steam, thereby increasing the volume of gas liquors; and (*c*) the adoption of the activated sludge method of sewage disposal. With vertical retorts, 76 gallons of spent liquor are produced per ton of coal, whereas with horizontal retorts 50 gallons are produced. The efficiency of the activated sludge process is likely to be affected by the presence of unduly high amounts of spent gas liquor in the sewage treated. Because of its high oxygen-absorption power the admixture of the spent liquor with crude sewage requires greater aerobic activity in the treatment of such mixtures, usually necessitating an increased purifying area.

It is possible, by several measures named, to diminish the amount of gas liquor produced; likewise to purify the liquor before its discharge into sewers. In the latter connection it is noted that if the volume of spent gas liquor does not exceed 1 per cent of the volume of domestic sewage and is introduced into the sewers in a small steady flow, the mixture can be purified without difficulty. Experiments made on treatment of the spent liquor, have indicated that when diluted until the 4-hour oxygen absorption value is 4,000 p. p. m., the liquor itself is amenable to biological filtration, which, at a rate of 15 gallons per cubic yard per day of 8 hours, reduced the oxygen absorbed by 90 per cent, and a second filtration at a rate of 12 gallons per cubic yard produced an effluent absorbing less than 20 p. p. m of dissolved oxygen.

In conclusion, it is stated that the discharge of spent gas liquors into sewers should be, as far as possible, uniform and proportionate to the flow of domestic sewage. The construction of equalizing tanks for this purpose offers no engineering difficulties.

Gas from the (Berlin) Sewage Settling Plant at Wassmansdorf. F Langbein. Gas. u. Wasserfach 70, 1109–18 (1927); cf. C. A. 21, 4000. Abstract by R. W. R. in *Chemical Abstracts*, vol. 22, No. 3, February 10, 1928, pp. 472–473.

"Sewage from the Neukoln and Shonberg areas of Berlin are clarified by settling tanks of the Ems or Imhoff type so that the effluent can be used for irrigation without 'baking' the soil. The Ems wells or basins are of the 'two-story' type, the settling basin comprising the upper part and the fermentation chamber the lower part. The separated slime slides through slits in the settling chamber into the fermentation chamber. About six months are required to 'work in' a fermentation chamber so that it is odorless and the cellulose fermentation is well established and capable of taking care of regulated amounts of fresh slime. At this time the gas produced by the fermentation consists of 70–80 per cent CH_4, with the balance largely CO_2. The resultant slime (after fermentation) is black, easily handled, smells slightly like rubber, and may be dried on suitable beds. It contains much humus and may be used agriculturally. Three hundred and fifty thousand cubic feet of sewage per day are treated in this way and fermenting capacity must be provided for three months. The slime is almost completely settled out in 45–50 minutes. The gas produced will average about 200,000 cubic feet per day, although 50 per cent greater may be produced in hot weather and 30 per cent less in cold weather. Part of the gas will be purified and used to

run pumping engines and the rest will be sold to Neukoln or used to generate electricity."

Sacramento to Go Afar for Water. Anon. *Water Works Engineering*, vol. 81, No. 2, January 18, 1928, pp. 79–80 and 93. (Abstract by Frank Raab.)

At present the city of Sacramento, Calif., is taking its water supply from the Sacramento River which is filtered and chlorinated. At times when the water in the river is very low, it is so highly charged with organic matter that it is "undesirable as a public water supply." Likewise "during such low water stages the rise of the tide reverses the flow of the river and occasionally carries a portion of the sewage from the outlet of the city sewers back to and into the water works intake." Silver Creek has been proposed as a new supply. This creek has its source in the mountains at an elevation of more than 5,000 feet. The project would require the building of several dams at an estimated cost of about $29,000,000. It is estimated that completion of the project will yield from 160,000,000 to 190,000,000 gallons daily which would supply a city of about 1,000,000 population. The water would have to be carried over a distance of 60 miles. The article gives estimates of the cost of construction of the entire project as well as a part of it which is all that is deemed necessary at first. The article also suggests the feasibility of a hydroelectric project. It is planned that the present filter plant be retained as a stand-by plant.

Five Years' Operation of a Rapid Sand Filtration Plant. Melville C. Whipple and Harold C. Chandler. *The American City*, vol. 38, No. 2, February, 1928, pp. 119-120. (Abstract by W. L. Havens.)

In order to prevent corrosion of the Cambridge, Mass., water system, a policy has been followed of furnishing water as nearly like the untreated supply as possible in mineral constituents and no worse in its tendency to dissolve metals. This treatment has consisted of the addition of from 50 to 150 pounds per million gallons of soda ash when alum alone is used as the precipitant, and from 35 to 65 pounds when using both alum and sodium aluminate. Odors and growths in the fresh pond reservoir have been controlled by the dosage of copper sulphate in amounts equal to 2 pounds per million gallons. The *B. coli* index per 100 c. c. averaged, during 1926-27, 10.0, 0.6, 0.1, and 0 for the raw, coagulated, filtered, and effluent samples, respectively. The total purification costs, exclusive of fixed charges, have amounted to about $11.50 per million gallons during the past three years.

Sand Filter Plant, Launceston, Tasmania. G. D. Balsille. *The Commonwealth Engineer*, 15, 95 8 (1927). Abstract by Edward Bartow in *Chemical Abstracts*, vol. 22, No. 3, February 10, 1928, p. 471.

"The water is taken from St. Patrick's River and passed through a mortar-lined channel in which green algæ grow. The algæ are sometimes present in sufficient quantity to decrease the flow of water through the channel. It has been noted that these algæ grow at alkalinities below 17 parts per million, and disappear at alkalinities above 18. Caddis worms, larvæ of a fly of the dragon family, feed on and destroy the algæ. Fresh soda is used to raise the alkalinity when it is too low for efficient treatment on the sand filters. Color is the index to show practical operation and it has been reduced 90 per cent throughout the year."

The Biological Effect of Colored Glass Windows in Waterworks. R. Kilkwitz. Gas u. Wasserfach 70, 1118 (1927). Abstract by R. W. Ryan in *Chemical Abstracts*, vol. 22, No. 3, February 10, 1928, p. 471.

"The use of colored glass windows, especially green, results in a marked decrease in the formation of algæ and mosses on wooden parts and walls."

A Comparison of the Temperature and Bacterial Count of Milk and Foam During Certain Stages of the Pasteurization Process. H. A. Whittaker and R. W. Archibald, U. S. Department of Agriculture, Tech. Bulletin No. 18, September, 1927. 11 pages. (Abstract by C. T. Butterfield.)

This article includes a complete description of the apparatus and methods employed, including the construction, placement, and operation of the thermocouples. Studies were made under conditions of normal operation at plants using the batch method of Pasteurization.

Bacterial count of foam was higher in every instance than that of the milk. During Pasteurization the bacterial count of milk decreased, while in 66.7 per cent of the tests the count in the foam increased. Bacterial count of foam varied greatly at different points in vats. Depth of foam did not affect bacterial reduction. If vats are tightly closed, bacterial content of foam is reduced.

The temperature of the air above the foam and of the foam itself was in every instance lower than that of the milk. The amount of foam varied in area from small patches to the entire surface of the vat and in depth from one-half to 4 inches. In no case was the foam raised to a satisfactory Pasteurizing temperature.

Controle Technique d'une Installation Municipale de Stérilisation d'Eau par l'Ozone. **(Control of a Municipal Plant for Purification of Water by Ozone.)** J. Salmon and P. Quarre. *Bulletin of Hygiene*, vol. 2, No. 12, December, 1927, pp. 978–979 (Abstract by C. R. Cox.)

A description of the water disinfecting plant of the city of Boulogne consisting of an ozonizer and the circulating system for ozonized air and the sterilizer or disinfecting unit. The ozonizer consists of a series of glass cylinders, a coaxial aluminum rod which serves as one electrode, and the aluminum inclosing case which serves as the other electrode. A single phase, 50-cycle, alternating current transformed to 8,000 to 10,000 volts is applied to the electrodes. Air, dried by calcium chloride, is forced through the cylinders in which the silent electrical discharge occurs, generating the ozone. This ozonized air is forced through a sterilizer, consisting of a vertical tower of reinforced concrete divided at intervals by horizontal partitions of perforated celluloid to insure intimate contact between the water and the ozonized air, both of which enter at the base of the tower The effluent from the sterilizer is tested periodically with starch iodide for free ozone and in the manner used for determining the residual chlorine in water. Bacteriological data are given indicating that the number of *B. coli* per liter was reduced from 1,000 to 0 and the gelatin count was reduced from 714 to 6 per c. c. The plant, with a capacity of 10,000 gallons per hour, consumes 0.65 k. w. hours of current to operate the ozonizer, consisting of two units of 3 cylinders each, and an additional 1.1 k. w. hour to operate the air compressor.

The Lethal Effect of Various Chemicals on Cyclops and Daphnia. B. A. Adams. *Water Works Engineering* 29, 361–4 (1927). Abstract by J. A. Kennedy in *Chemical Abstracts*, vol. 22, No. 3, February 10, 1928, p. 473.

"All sterilizing agents used in water treatment are lethal to *Cyclops* and *Daphnia* in the water of the Nile. Cl and hypochlorite mixed with $(NH_4)_2SO_4$ is the most lethal and is effective in concentration of 1 in 1,000,000. Cl or hypochlorite alone is effective with a concentration of 1 in 500,000. $KMnO_4$, chloramine-T, and acridine are effective in concentrations of 1 in 200,000. Phenol and cresols are lethal in concentrations of 1 in 100,000. $CuSO_4$ has some effect, but formalin has no effect in a concentration of 1 in 100,000. Lime in excess or not quite in excess is very effective."

DEATHS DURING WEEK ENDED APRIL 7, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended April 7, 1928, and corresponding week of 1927. (From the Weekly Health Index, April 11, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended Apr. 7, 1928	Corresponding week, 1927
Policies in force	70,570,508	67,271,091
Number of death claims	12,812	13,077
Death claims per 1,000 policies in force, annual rate	9.5	10.1

[1] Annual rate per 1,000 population.
[2] Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
[3] Deaths for week ended Friday, Apr. 6, 1928.
[4] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31; Baltimore, 15; Birmingham, 39; Dallas, 15; Fort Worth, 14; Houston, 25; Indianapolis, 11; Kansas City, Kans., 14; Knoxville, 15; Louisville, 17; Memphis, 38; Nashville, 30; New Orleans, 26; Richmond, 32; and Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

CURRENT WEEKLY STATE REPORTS

These reports are preliminary and the figures are subject to change when later returns are received by the State health officers

Reports for Weeks Ended April 16, 1927, and April 14, 1928

SUMMARY OF MONTHLY REPORTS FROM STATES

The following summary of monthly State reports is published weekly and covers only those States from which reports are received during the current week.

State	Meningococcus meningitis	Diphtheria	Influenza	Malaria	Measles	Pellagra	Poliomyelitis	Scarlet fever	Smallpox	Typhoid fever
January, 1928										
Colorado	25	82	3		353		8	594	102	10
February, 1928										
Colorado	21	70	15		240		1	509	60	4
District of Columbia	0	134	9		249		0	193	0	1
March, 1928										
Arizona	21	29	3		109		1	89	132	8
Connecticut	4	108	199		1,574		2	453	4	3
Nebraska	5	52	257		137		4	582	255	1
North Dakota	12	22	12		15		1	309	6	10
Vermont	0	3			325			60	0	1

January, 1928

	Cases
Colorado:	
Botulism (December)	3
Chicken pox	474
German measles	16
Impetigo contagiosa	5
Mumps	248
Scabies	4
Trachoma	2
Whooping cough	82

February, 1928

	Cases
Chicken pox:	
Colorado	227
District of Columbia	97
German measles:	
Colorado	6
Impetigo contagiosa:	
Colorado	14
Mumps:	
Colorado	59
Paratyphoid fever:	
Colorado	1

February, 1928—Continued

	Cases
Puerperal fever:	
Colorado	1
Scabies:	
Colorado	7
Septic sore throat:	
Colorado	2
Trachoma:	
Colorado	1
Whooping cough:	
Colorado	99
District of Columbia	34

March, 1928

	Cases
Chicken pox:	
Arizona	58
Connecticut	417
Nebraska	330
North Dakota	66
Vermont	170

March, 1928—Continued

	Cases
Conjunctivitis:	
Connecticut	2
Dysentery (bacillary):	
Connecticut	1
German measles:	
Connecticut	11
North Dakota	4
Impetigo contagiosa:	
North Dakota	5
Lead poisoning:	
Connecticut	1
Lethargic encephalitis:	
Connecticut	2
North Dakota	7
Mumps:	
Arizona	56
Connecticut	1,269
Nebraska	437
North Dakota	94
Vermont	448

March, 1928—Continued

	Cases
Paratyphoid fever:	
Arizona	1
Rabies (in animals):	
Connecticut	1
Septic sore throat:	
Connecticut	5
Nebraska	17
Vermont	14
Tetanus:	
Connecticut	1
Trachoma:	
Arizona	21
Trichinosis:	
Connecticut	4
Vincent's angina:	
North Dakota	1
Whooping cough:	
Arizona	23
Connecticut	572
Nebraska	59
North Dakota	46
Vermont	141

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 99 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,500,000. The estimated population of the 93 cities reporting deaths is more than 30,800,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended March 31, 1928, and April 2, 1927

	1928	1927	Estimated expectancy		1928	1927	Estimated expectancy
Cases reported				*Cases reported*—Contd.

City reports for week ended March 31, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during non-epidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended March 31, 1928, compared with those for a like period ended April 2, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1927 and 1928, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,050,000 in 1927 and 31,657,000 in 1928. The 95 cities reporting deaths had nearly 30,370,000 estimated population in 1927 and nearly 30,961,000 in 1928. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, February 26 to March 31, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

TYPHUS FEVER ON VESSEL

Steamship "Gaika"—At Durban, Union of South Africa, from Island of Mauritius.—Under date of March 9, 1928, the arrival of the steamship *Gaika* from Island of Mauritius, with a case of typhus fever on board, was reported from Durban, Natal, Union of South Africa. The *Gaika* left London December 22, 1927, for Mauritius, passed Las Palmas, Canary Islands, December 29, 1927, Cape Town January 18, arrived at Mauritius January 31, 1928, and sailed for London via Durban and ports February 8, 1928.

THE FAR EAST

Report for the week ended March 17, 1928.—The following report for the week ended March 17, 1928, was transmitted by the eastern bureau of the health section of the secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Aden Protectorate.—Aden.
India.—Bassein, Bombay, Rangoon.
Ceylon.—Colombo.
Dutch East Indies.—Cheribon.

CHOLERA

India.—Bombay, Tuticorin, Rangoon.
Siam.—Bangkok.
French Indo-China.—Saigon.

SMALLPOX

Iraq.—Basrah.
India.—Bombay, Madras, Rangoon.
French India.—Pondicherry.
Straits Settlements.—Singapore.
French Indo-China.—Tourane.
Dutch East Indies.—Belawan-Deli, Banjermasin.
China.—Canton, Shanghai, Hong Kong.

Returns for the week ended March 17 were not received from the following ports:

India.—Calcutta.
Dutch East Indies.—Samarinda.
Kwantung.—Port Arthur, Dairen, towns of the South Manchurian railway zone.
Union of Socialist Soviet Republics.—Vladivostok.

AUSTRIA

Communicable diseases—January 1 to 28, 1928.—During the period January 1 to 28, 1928, communicable diseases were reported in Austria as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Cerebrospinal meningitis	6	1	Puerperal fever	18	12
Chicken pox	789		Scarlet fever	496	4
Diphtheria	665	13	Trachoma	52	
Dysentery	12		Typhoid fever	61	5
Paratyphoid fever	29	2	Typhus fever	[1] 1	

[1] Vienna.

CANADA

Provinces—Communicable diseases—Week ended March 24, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from seven Provinces of Canada for the week ended March 24, 1928, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal meningitis			2	1				3
Influenza	15			12				27
Smallpox				35		7	20	62
Typhoid fever		10	8	2			4	24

Quebec Province—Communicable diseases—Week ended March 31, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended March 31, 1928, as follows:

Disease	Cases	Disease	Cases
Chicken pox	221	Scarlet fever	90
Diphtheria	52	Smallpox	35
German measles	19	Tuberculosis	54
Influenza	5	Typhoid fever	15
Measles	273	Whooping cough	20
Poliomyelitis	1		

CZECHOSLOVAKIA

Communicable diseases—February, 1928.—During the month of February, 1928, communicable diseases were reported in Czechoslovakia, as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Anthrax	5	1	Paratyphoid fever	4	1
Cerebrospinal meningitis	14	6	Puerperal fever	42	21
Diphtheria	870	73	Scarlet fever	1,315	29
Dysentery	8	1	Trachoma	198	
Malaria	3		Typhoid fever	452	44

DENMARK

Communicable diseases—January, 1928.—During the month of January, 1928, communicable diseases were reported in the Kingdom of Denmark, as follows:

Disease	Cases	Disease	Cases
Anthrax	1	Paratyphoid fever	3
Cerebrospinal meningitis	12	Puerperal fever	22
Chicken pox	99	Pneumonia	480
Diphtheria	681	Scabies	1,082
Erysipelas	281	Scarlet fever	304
Influenza	5,877	Tetanus	4
Lethargic encephalitis	11	Tuberculosis, pulmonary	270
Measles	6,883	Typhoid fever	8
Mumps	704	Whooping cough	1,469

Population of Denmark 3,491,000.

DOMINICAN REPUBLIC

Leprosy.—A report dated March 5, 1928, states that there were at that time 56 leper patients in the National Leprosarium and that about 20 lepers were isolated in their homes in the Dominican Republic. The National Leprosarium is located about 17 kilometers from Santo Domingo. The population of the Dominican Republic is said to be about 1,000,000.

FRENCH SUDAN AND UPPER VOLTA

Smallpox—February 16–29, 1928.—During the two weeks ended February 29, 1928, smallpox was reported present in the French Sudan with 1 case and in the Upper Volta with 5 cases.

ITALY

Communicable diseases—January 2–15, 1928.—During the two weeks ended January 15, 1928, communicable diseases were reported in the Kingdom of Italy, as follows:

Disease	Jan. 2-8, 1928		Jan. 9-15, 1928	
	Cases	Communes affected	Cases	Communes affected
Anthrax	28	26	25	28
Cerebrospinal meningitis	7	7	19	15
Chicken pox	307	108	365	125
Diphtheria	435	264	480	272
Dysentery	5	3	2	2
Lethargic encephalitis	3	3	6	6
Measles	2,135	277	2,506	297
Poliomyelitis	10	9	9	9
Rabies			1	1
Scarlet fever	369	146	396	174
Smallpox	1	1	2	2
Typhoid fever	548	298	477	276

JAMAICA

Smallpox (alastrim)—February 26–March 24, 1928.—During the period February 26 to March 24, 1928, 11 cases of smallpox, reported as alastrim, were notified in the island of Jamaica, occurring in localities not included in the Kingston area.

Other communicable diseases.—During the same period, other communicable diseases were reported in the island as follows:

Disease	Kingston	Other localities	Disease	Kingston	Other localities
Chicken pox	1	11	Puerperal fever		1
Dysentery	10	25	Tuberculosis	17	48
Erysipelas		2	Typhoid fever	20	63

Population: Kingston, 62,707; island, 926,000.

LATVIA

Communicable diseases—January, 1928.—During the month of January, 1928, communicable diseases were reported in the Republic of Latvia as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	4	Poliomyelitis	1
Diphtheria	42	Puerperal fever	4
Erysipelas	17	Scarlet fever	240
Influenza	36	Tetanus	1
Leprosy	6	Trachoma	22
Measles	239	Typhoid fever	60
Mumps	7	Whooping cough	46

Population: 1,950,000.

MADAGASCAR

Plague—January 1 to 15, 1928.—During the 15 days ended January 15, 1928, 199 cases of plague with 188 deaths, were reported in the island of Madagascar. The distribution of occurrence by Provinces was as follows: Ambositra—cases 54, deaths 54; Antisirabi—cases 43, deaths 43; Itasy—cases 13, deaths 13; Moramanga—cases 19, deaths 19; Tananarive—cases 70, deaths 59, including Tananarive Town with 5 cases, 4 deaths. The distribution by type was as follows: Bubonic, 123; pneumonic, 41; septicemic, 35.

MALTA

Communicable diseases—January-February, 1928.—Communicable diseases were reported in the island of Malta during the months of January and February, 1928, as follows:

Cases reported

Disease	January, 1928	February, 1928	Disease	January, 1928	February, 1928
Broncho-pneumonia	11	11	Pneumonia	4	5
Chicken pox	24	14	Puerperal fever		1
Diphtheria	11	4	Scarlet fever	4	6
Erysipelas	2	2	Trachoma	21	26
Influenza		1	Tuberculosis	17	15
Lethargic encephalitis	1		Typhoid fever	37	29
Malta (undulant) fever	38	39	Whooping cough	8	2
Measles	2				

Population (civil), estimated, 227,440.

MEXICO

State of Jalisco—Smallpox—April 5, 1928.—On April 5, 1928, an epidemic of smallpox was reported in eastern Jalisco, Mexico.

PERU

Arequipa—Mortality—February, 1928.—During the month of February, 1928, 73 deaths from all causes, including 12 deaths from gastroenteritis and 22 from tuberculosis, were reported at Arequipa, Peru.

SENEGAL

Plague—Smallpox—February 16-29, 1928.—During the two weeks ended February 29, 1928, 17 cases of plague with 13 deaths were reported in the interior of Senegal. During the same period smallpox was reported in the interior of Senegal, in the district of Dakar, and in Mauretania.

UNION OF SOUTH AFRICA

Plague—Orange Free State—Week ended February 25, 1928.—During the week ended February 25, 1928, a case of plague was reported in the Orange Free State, occurring on a farm.

Smallpox.—During the same period an outbreak of smallpox was reported in the Orange Free State.

Typhus fever.—During the same period typhus fever was reported in one district of the Cape Province and in two districts of the Orange Free State.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst. Surg Gen. R. C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

PUBLIC HEALTH REPORTS

VOL. 43 APRIL 27, 1928 NO. 17

CURRENT WORLD PREVALENCE OF COMMUNICABLE DISEASES [1]

United States, March 11-April 7, 1928

The mortality in large cities increased during March, the average death rate in 68 large cities (annual basis) rising from 14.3 per 1,000 in the week ended March 10 to 15.3 in the week ended March 31, and to 15 in the week ende[illegible] 7. The seasonal increase continued unusually late, as th[illegible]ortality normally is expected by the middle of March, a[illegible]ge death rate in the cities for the two weeks ended April 7 [illegible]er than that for the corresponding weeks in any of the prece[illegible]g seven years except 1926, when influenza was epidemic. Nevertheless, as [illegible] result of the unusually favorable mortality in January and Feb[illegible]ary, the average death rate in the 68 cities in the first 14 weeks o[illegible] he current year (14.2) is as low as that in 1924 and lower than that in any recent years except 1927 and 1921.

Influenza and pneumonia.—Reported cases of influenza increased continuously up to the first week in April, when 31 states reported 3,386 cases, as compared with 2,163 cases in the week ended March 3. Some increase occurred in most of the States reporting, which are distributed throughout all sections of the United States. The mortality from influenza and pneumonia combined increased during the first half of March and in the week ended March 17, the latest available, the mortality was higher than in the corresponding week of 1927 in the cities reporting in each of the geographical districts except in the South Atlantic and Pacific States.

The excess mortality over the corresponding week of a year ago was especially marked in the East and West South Central States and in the Mountain States.

Meningococcus meningitis.—More cases of meningococcus meningitis have been reported during 1928 than in the corresponding weeks of either of the preceding two years. The number of cases increased quite sharply during March, as is shown in the accompanying table, and the cases reported in the four weeks ended April 7 indicate a prevalence more than twice that of a year ago.

[1] From the Office of Stati[illegible] Investigations, United States Public Health Service.

Number of cases of meningococcus meningitis reported by 42 States and the District of Columbia

Four weeks ended—	1926	1927	1928
Mar. 10	226	228	382
Apr. 7	215	255	577

Although some seasonal increase in the disease in the winter and spring months is normally expected, the rise in recent weeks has been unusually rapid; and it has been very general, about one-half of the States reporting 50 to 100 per cent increase in cases in the four weeks ended April 7 over the preceding four weeks. The highest incidence rate for the first 12 weeks of 1928 [1] occurred in the Mountain States and the next highest in the Pacific Coast States, while a low incidence is indicated for the South Cen[illegible] South Atlantic States and New England. The a[illegible] annual basis) for the 42 States was 4.9 per 100,000 p[illegible]. Apparently, it is a characteristic of the disease that wi[illegible] [illegible]arated places are often simultaneously affected and that only a rather small proportion of the population contract it.

Smallpox.—The number of cases of smallpox reported by 42 States and the District of Columbia has varied about a level of 1,100 cases weekly since early in January. For the four weeks ended April 7, the reported cases numbered 4,743, as compared with 3,933 in the corresponding period of 1927 and 3,370 in 1926. Several States reported an increase in the number of cases in the four weeks ended April 7 over the preceding four-week period; these include Arkansas, New Mexico, Colorado, California, Kansas, Missouri, Indiana, New Jersey, and West Virginia. In each of these States, except Indiana, the prevalence of smallpox was greater in the first quarter of 1928 than in 1927, as was true also of Arizona, Connecticut, Illinois, Iowa, Louisiana, Montana, Nebraska, North Carolina, Oklahoma, Oregon, Tennessee, Utah, Wyoming, and Wisconsin.

Marked improvement is indicated in the smallpox situation in Alabama, Florida, Georgia, and Virginia, where the disease was widely prevalent in 1927.

Scarlet fever.—The reported incidence of scarlet fever during March was approximately the same as it was in February, but the number of cases reported in the first week of April showed a slight decline. In a number of States, especially in those west of the Mississippi River, the seasonal decline was quite definite, but in others it was not yet apparent. In general, a gradual decrease in the number of cases may be expected throughout the spring months.

---

[1] See Public Health Reports for April 6, 1928, p. 807.

Diphtheria.—The number of cases of diphtheria reported each week by 42 States continued to decline during March, and in the first week of April the reported cases numbered approximately 1,400, as compared with about 1,700 in the week ended March 10. The decline has been general and is normal for the season of the year.

Measles.—Measles incidence continued on a high level throughout March and in the first week of April, with the number of cases reported each week by 38 States averaging about 18,000. In a number of southern States in which the disease has been quite prevalent, the maximum incidence appeared to have been passed, notably in Alabama, Arkansas, Louisiana, Maryland, North Carolina, and South Carolina; but for Massachusetts, New York, New Jersey, Pennsylvania, Michigan, and Missouri the latest reports had shown no decline in the number of cases.

Poliomyelitis —One or more cases of poliomyelitis were reported during the four weeks ended April 7 by 34 States, which reported 122 cases in this period. Although the number of cases is fewer than that reported in the preceding four-week period, it is still more than double the number for the corresponding weeks a year ago In these four weeks, California reported 12 cases, New York 15, Ohio 10, Massachusetts and South Dakota 7 each, and Oregon 6 cases.

Typhoid fever.—The typhoid fever incidence has been lower throughout the first quarter of the current year than in either of the preceding two years. Cases reported by 41 States in the two weeks ended April 7 were somewhat more numerous than in the preceding two weeks—340 as compared with 270. The increase was due to very small increases in a number of States

Foreign Countries [1]

The general prevalence of certain epidemic diseases in most foreign countries during January and February is summarized below.

Cholera.—Cholera was reported during the four weeks ended February 25 from very few towns in the Far East. One case was reported at Singapore, 1 at Karikal, 8 cases were reported at Saigon, 102 at Bangkok, and cases were reported from several ports in India. The incidence at Bangkok was slightly higher than in the preceding four weeks; and the same was true at Calcutta, where 147 deaths occurred in these four weeks.

The cholera incidence in India continued to decline in January, but the disease was still widespread in two areas—Bengal and the Madras Presidency. Of the 10,154 cases reported in the first three weeks of 1928, 7,787 occurred in the Bengal-Assam-Orissa areas, 2,236 in Madras Presidency, and only 131 elsewhere in India.

[1] Data from the Monthly Epidemiological Report of the Health Section of the League of Nations' Secretariat, Mar. 15, 1928, supplemented by information published in the PUBLIC HEALTH REPORTS.

The cholera outbreak in Annam, reported last month, declined sharply in February; 59 cases were reported in the period February 1–20 as compared with 188 cases in the preceding 20 days. In Cochin-China the number of cholera cases was still increasing at the beginning of February, but the maximum seemed to have been passed in the first 10 days, when 178 cases were reported. The disease is not prevalent in the remainder of French Indo-China; a few cases were reported in Cambodia and none in Laos or Tonkin.

Plague.—No plague cases were reported in February in Mediterranean ports. At Suez 15 cases were reported between January 1 and February 20; all occurred inland 2 miles or more from the port.

The plague outbreak in Aden increased early in February, but no further increase was indicated by the reports for the latter part of the month. Up to March 3, 382 cases and 218 deaths were reported—figures much in excess of those for any previous outbreak since that of 1900. It is reported that the first cases occurred among the coal coolies and that the European quarters and wharves were free from infection up to February 6. Infected rats have been found, but not in large numbers.

The plague incidence in India as a whole during the first three weeks of 1928 was higher than during the corresponding period of the preceding year, but lower than in the years from 1923 to 1925. In the Punjab the plague situation remains very favorable, and only once before, in 1922, has the incidence been so low. More cases were reported, on the other hand, in the United Provinces than during either of the two preceding years. Two areas of these provinces are chiefly affected, one in the north around Bareilly, and another larger area in the east, including the districts of Azamgarh, Ghazipur, Fyabad, and Basti. Plague is present also in Muzaffarpur and other districts of Bihar, to the east of this area, but the incidence is well below the normal.

Deaths from plague in the Provinces of India during three weeks in January in the years 1924–1928

Provinces	1924	1925	1926	1927	1928
	Dec 30–Jan 19	Jan 4–24	Jan 3–23	Jan 2–22	Jan. 1–21
North-West Frontier Province	88	90	0	0	0
Punjab, Delhi, and Punjab States	1,992	2,648	1,426	392	200

Burma	1,048	209	438	157	390
Other Indian States	139	140	162	63	21
Total	9,306	10,493	6,204	3,072	4,296

Hyderabad city is the scene of a more severe plague outbreak than has occurred there for many years past. The number of cases began to increase in November and appeared to have reached its maximum about the middle of January, which is usually the season of greatest prevalence in Hyderabad. Plague was prevalent also in the adjacent cantonment of Secundarabad.

Plague cases and deaths reported in Hyderabad City and suburbs by fortnightly periods, November 6, 1927, to January 14, 1928

Date	Cases	Deaths
November 6-19	96	71
November 20-December 3	197	126
December 4-17	407	281
December 18-31	900	693
January 1-14	1,393	1,108

In the Bombay Deccan, where epidemics normally reach their height in September or October, plague was unusually prevalent in January. The prevalence was high also in the Madura district in the extreme south of India.

Plague is more prevalent than usual in Upper Burma, which in the past has suffered much less than Lower Burma from this disease. During the first three weeks of January, 175 deaths from plague were reported in Lower Burma and 715 in Upper Burma. The last relatively severe epidemic in Upper Burma was in 1924, when the city of Mandalay was seriously affected.

The winter rains have been much in excess of the normal in most parts of India, and particularly over a wide belt stretching from the United Provinces in the north to the Deccan in the south. In northwestern India they have been about normal, i. e., scanty; and in Bengal, Assam, and Orissa, where there is no plague, they have been much less than usual. It has been long observed that a very wet winter favors the development of plague outbreaks in the following months. The plague incidence, which last autumn was unusually low, seems to have been unfavorably influenced in several areas, and especially in the eastern part of the United Provinces, in Hyderabad, the Bombay Deccan, and Upper Burma, by the humidity resulting from this increased rainfall.

Yellow fever.—Matadi, in Belgian Congo, was officially declared free from yellow fever on February 19; no fresh case had been reported since February 2.[1] The outbreak lasted from December 22 to February 2, and 19 cases with 10 deaths were notified among the white population and 18 cases with 14 deaths among negroes. There were 3 cases with 2 deaths at Boma. No yellow fever case has been reported elsewhere in Africa since the beginning of 1928.

[1] A case of yellow fever was reported at Matadi Feb. 24, 1928.—Ed.

Smallpox.—No change in the prevalence of smallpox in England and Wales occurred in February; 1,516 cases were reported in the four weeks ended February 25, as compared with 1,460 cases in the preceding four weeks, and 1,810 cases during the corresponding period of 1927. The chief centers of infection were still in the north of England and in South Wales. During the first eight weeks of the year seven deaths from smallpox occurred in the large towns, five of these being at Bradford.

On the European Continent, smallpox cases have occurred only sporadically for the most part. In Spain, 53 deaths were reported for November, 1927, and in Portugal 143 smallpox cases with 22 deaths were reported in January. Eleven cases of smallpox were reported in France in January. Smallpox is fairly widespread in the eastern part of the Union of Soviet Socialist Republics, in the Tartar, Bashkir, and Votyak Republics and in Viatka and the Ural area.

The smallpox situation in Algeria and Morocco improved markedly in January. Fifty-five cases were reported in Morocco and 57 in Algeria in January, as against 398 and 209, respectively, in December. The outbreak of virulent smallpox which began in June, 1927, in northern Rhodesia increased during the last months of the year; 1,079 cases and 182 deaths were reported during the whole of 1927, as compared with 305 cases and 8 deaths the preceding year.

Influenza.—Up to the end of February there had been no influenza outbreaks reported in Europe. Deaths from influenza in large towns of England and Wales averaged 94 a week between January 22 and March 3, and show no tendency to increase or decrease. Deaths ascribed to influenza in large German towns averaged 51 during the first six weeks of the year; their number did not increase during this period.

The number of cases reported in January in Denmark, Sweden, and Finland was about normal for nonepidemic years. In Leningrad 63 deaths were attributed to influenza in January, which is not indicative of epidemic prevalence. In Hungary, only 35 deaths were ascribed to influenza in January, as against 223 during the corresponding month of the preceding year.

Influenza was very prevalent in Japan in January and February, but on March 17 conditions were reported to have greatly improved. From January 1 to February 10, 1928, there were 27,411 cases of influenza and 395 deaths, according to a statement from the Home Office of Japan.

Acute poliomyelitis.—Poliomyelitis was more prevalent in 1927 than in any of the preceding three years in Germany, Austria, Rumania, and Canada. There was a decrease in the incidence in England, France, Denmark, and Australia, and not much change

in other countries. The number of cases reported in countries where this disease is notifiable by law is shown in the accompanying table.

Poliomyelitis cases reported in various countries, 1924–1927

Country	Number of cases			
	1924	1925	1926	1927
EUROPE				
Germany	498	386	1,614	2,740
England and Wales	860	422	1,297	899
Austria	19	15	47	149
Denmark	152	113	64	34
Finland	45	28	12	52
France	216	222	214	156

Rumania				2,161
Sweden	653	517	338	385
Switzerland	108	93	97	132
AMERICA				
Canada	217	167	113	610
United States	5,078	5,429	2,543	9,737
AUSTRALASIA				
Australia	238	261	174	67
New Zealand	73	1,319	29	43

The Rumanian epidemic began at Bucharest and was most widespread there and in the neighboring departments. Three-fourths of the cases occurred in 7 of the 76 departments into which the country is divided. Poliomyelitis had theretofore been very rare in Rumania. The proportion of very young children attacked was unusually large. At Bucharest 90 per cent of the cases were under 4 years of age, and the maximum incidence was between 1 and 2 years of age.

Diphtheria.—The diphtheria incidence was higher than usual during the latter part of 1927 and the beginning of 1928 in nearly all European countries.

The incidence of diphtheria in Poland and Italy was higher this winter than at any time during the past five years. The number of cases reported in Italy during the last quarter of 1927 was 6,924, as compared with 4,342 during the corresponding period of the preceding year. In Germany the incidence was about the same as that during the winter 1924–25, but was lower than in 1921–22. In England the number of cases was about the same as in 1922. A general increase of diphtheria also affected North Africa. In Egypt 1,251 cases were reported during the last quarter of 1927, as compared with 533 during the corresponding period of 1926.

The increase of diphtheria in Australia, which began during the fourth quarter of 1926 and reached its maximum in April, 1927, subsided toward the end of that year; 1,537 cases were reported during the last quarter of 1927, as compared with 2,270 during the corresponding period of the preceding year. The number of cases reported in 1927 was about the same as in 1923 and 1924, but less than half the number reported in 1921.

CURRENT STATE MORTALITY STATISTICS

For the information of public health officials and others interested, the data in the following tables have been taken from the monthly mortality reports of State health departments for the latest month for which published records are available. Statistics of most communicable diseases are not included, since they are available in other tabulations in the Public Health Reports. Statistics of deaths from other causes are limited for the most part to those causes which appear in the State reports. In the case of States which publish detailed mortality reports each month, the record of only the principal groups of causes and certain important specific causes have been used.

For purposes of comparison, the mortality records for the corresponding month in a few preceding years have been compiled. The rates have been computed upon the populations as estimated for July 1 of each year represented.

These tabulations will be enlarged as the current data on mortality from additional States become available.

Summaries of annual mortality statistics for 1927 are appended whenever the data are available from the States, and comparisons with several prior years are included when practicable.

Accidents	66.8	70.8	72.6	70.6	71.6

[1] Rate per 1,000 living births.

Bulletin No. 7, March 19, 1928, published by the Kansas State Department of Health, comments as follows on the 10 principal causes of death in Kansas in 1927:

Eighteen thousand seven hundred and thirteen deaths were recorded in the State of Kansas during the year 1927, and of that number, 11,251 resulted from 10 diseases, or, as we may term them, the "Ten principal causes of death." Listed in order of their occurrence, they are as follows:

Mortality from 10 principal causes of death in Kansas in 1927

Disease	1927		1926		1925	
	Death rate per 100,000	Rank	Death rate per 100,000	Rank	Death rate per 100,000	Rank
Organic heart disease	143.1	1	131.9	1	116.3	1
Cancer, all forms	100.6	2	91.9	3	84.3	3
Apoplexy	100.2	3	101.1	2	95.7	2
Bright's disease	83.9	4	89.1	4	78.1	4
Pneumonia, all forms	50.9	5	59.1	5	66.0	5
Tuberculosis, all forms	35.3	6	41.0	7	43.0	6
Premature births	30.9	7	32.6	8	32.7	8
Influenza	25.8	8	49.6	6	30.2	9
Diarrhea and enteritis	21.1	9	29.5	9	37.0	7
Senility	20.7	10			20.0	10
Arteriosclerosis			15.7	10		

* * * The 10 principal causes were the same for the three years, except in 1926, arteriosclerosis replaced senility, or old age. * * *

Organic heart disease caused 2,616 deaths, or 14.2 per cent of the total deaths, the rate being 142.3 per 100,000 population. Deaths from heart disease have shown a steady increase from year to year, and this has been especially so the past five years. The comparison from year to year since 1912, the first year for which accurate vital statistics are available, should be interesting:

Mortality from organic heart disease in Kansas

Year	Number of deaths	Rate per 100,000	Per cent of total deaths	Year	Number of deaths	Rate per 100,000	Per cent of total deaths
1912	1,489	89.1	8.6	1925	2,286	126.0	12.2
1917	2,003	115.3	9.5	1926	2,491	136.6	12.9
1922	1,952	108.0	10.3	1927	2,616	142.3	14.2
1924	2,134	116.3	11.9				

It will be noticed that heart-disease deaths have shown a more than 1 per cent increase in 1927 over the year 1926. In 1925, 73 per cent of heart-disease deaths were in the age group 60 to 80 years.

Cancer ranked second with 1,839 deaths, or 9.8 per cent of the total. The rate was exactly 100 per 100,000 population. This is the largest number of deaths and also the highest rate on record in the State. This disease has shown a steady increase in the number of deaths. In both 1925 and 1926, cancer ranked third with 1,529 and 1,674 deaths respectively. In 1912, there were 1,056 deaths or 6.1 per cent of the total. Cancer occurs infrequently prior to 30 years of age, and the great majority of deaths occur after 50.

Apoplexy, with 1,832 deaths, showed a decrease of 9 from the previous year, but an increase of approximately 100 over the year 1925; 9.7 per cent of deaths in 1927 resulted from this disease. The number of deaths, the rate, and the per cent of total deaths, as in the previous diseases listed, are the highest on record.

Bright's disease deaths totaled 1,534, 8.1 per cent of the total, and the rate was 83.4. There were 89 fewer deaths than in the year 1926, and the rate was 5.6 less per 100,000.

Pneumonia deaths totaled 931, the second-lowest number on record, 870 deaths occurring in 1909. The rate, however, was the lowest on record, the difference being readily explained by the greater population in 1927. There were 146 fewer deaths than in 1926 and 265 fewer than in 1925.

Tuberculosis with 645 deaths ranked sixth, the same as in 1925. This disease, however, ranked seventh in 1926. Tuberculosis caused only 3.4 per cent of the total deaths.

Premature births totaled 564, a decrease of 30 from the preceding year, and 31 fewer than in 1925.

Influenza, with 526 deaths, ranked eighth in 1927, sixth in 1926, and ninth in 1925.

MICHIGAN 1922-1927

Michigan Public Health for March, 1928, published by the Michigan State Department of Health, shows the general and infant mortality rates for 1927 for the State. The rates for previous years are shown for purposes of comparison.

Mortality in Michigan in 1927, and comparison with previous years

	1927	1926	1925	1924	1923	1922
	Death rate per 1,000					
All causes	11.5	12.7	11.8	12.2	12.8	11.2
	Rate per 1,000 live births					
Infant mortality	67.8	77.6	75.6	72.2	80.4	74.7

NEW JERSEY

The Public Health News, of January–February, 1928, published by the department of health of the State of New Jersey, makes the following comment on mortality in 1927 in New Jersey:

The New Jersey death rate for 1927 is the lowest in the 50-year records of vital statistics in this State. Provisional figures show that there were 11.43 deaths per thousand population, a slight improvement over the previous low rate of 1921, which was 11.49. Despite the increased population since the State department was organized in 1878, there were fewer deaths from typhoid fever and measles than during any preceding year—typhoid fever, 51; measles, 21. Tuberculosis and cancer show a slightly increased death rate.

The number of deaths of infants under one year per thousand live births was 61. The infant death rate has shown a steadily downward trend; 14 years ago it was exactly double the present rate, and for 1926 the rate was 70, or nine points higher than the rate for 1927.

Unfortunately, a similar decline is not evident in the number of mothers who died during childbirth. The rate this year of 6.1 is an increase over last year's rate of 5.4.

During 1927 approximately 72,800 births were reported, which is a rate of 20 per thousand inhabitants. The total number of births increased 428 over the previous year, but the larger estimated population of the State caused the rate to decline a fourth of a point. The birth rate has declined almost without exception since 1921.

In brief, the year shows the lowest general and infant death rate ever recorded.

NEW YORK STATE (EXCLUSIVE OF NEW YORK CITY) 1923-1927

Since the publication in the Public Health Reports for March 30, 1928, of annual figures from the Health News, the following provisional data are given in the Supplement to the Vital Statistics Review, March, 1928, because they are more complete for New York State (exclusive of New York City).

Mortality in New York State (exclusive of New York City) in 1927 compared with previous years

	Death classification, by cause or age	1927	1926	1925	1924	1923
		Rate per 1,000				
1-205	All causes	12.8	14.0	13.3	13.3	14.8

[1] Except the puerperal state and diseases of early infancy.
[2] Rate per 1,000 total births.
[3] Rate per 1,000 live births.

The 1927 rates both for births and deaths are the lowest ever recorded in Pennsylvania, and the death rates for a number of the more important causes of death have also established new low records. The only important high record set in 1927 was for automobile deaths on the basis of 100,000 population, but when the automobile death rate is computed on the basis of 1,000 registered motor vehicles in the State, even this becomes a new low record of 1.1 as compared with 1.2 in 1925 and 1926.

The 1927 birth rate as given in the table is the same as in 1926; but if the computation were carried out one more decimal place it would be slightly lower than in 1926, which was the previous low record. But the general death rate, and particularly the infant death rate, shows such a remarkable drop that the population increase in 1927 from the excess of births over deaths was well above the average of the past 22 years.

The low death rate of 11.4 per 1,000 inhabitants, was due largely to the relatively low prevalence of disease of the respiratory system. The decrease in deaths from pneumonia and influenza alone account for 55 per cent of the total reduction in the deaths as compared with 1926. The death rate from pneumonia was only 98.1 per 100,000 population, as compared with a previous low record of 128 in 1925. Tuberculosis also shows a new low record, both for pulmonary tuberculosis and for other forms of the disease. The rate of 69.9 per 100,000 for all forms of tuberculosis may be compared with the rate of 150.9 in 1906. In these 22 years tuberculosis has declined from the first to the sixth cause of death.

Typhoid fever, with a new low rate of 2.7 per 100,000, is no longer an important factor in the mortality statistics of Pennsylvania. Smallpox, once the terror of mankind, has claimed no victims in Pennsylvania in more than two years. Measles shows a low death rate in 1927; but this disease comes in cycles, so it may be expected to return in 1929. Scarlet fever and whooping cough also will probably return again as they have in the past after years of light incidence. Diphtheria was the only one of the acute infections of childhood to show an increase in 1927 over 1926, but this increase was slight and came after five successive years in which new low records for diphtheria deaths were established.

For the diseases of advanced years the record of 1927 was not so good. Heart disease, now the leading cause of death, dropped very slightly from the high record of 1926. Likewise the death rates for cancer and diabetes were exceeded only by those of 1926. For nephritis and cerebral hemorrhage the death rates were above the average of 22 years.

The maternal mortality rate still stands at 6.1 per 1,000 total births. This rate is the same as for 1926 and 1925, and is but slightly below the average of the preceding 21 years. Likewise the death rates from violent causes show little change. There was a slight decrease in the rates for accidents on railroads and in mines and quarries, but these decreases were offset by increases in automobile deaths and accidents of other sorts. The rates for homicides, suicide, and accidental drowning show no material changes.

THE PRACTICAL APPLICATION OF TWO QUALITATIVE TESTS FOR HCN IN SHIP FUMIGATION

By G. C. Sherrard, *Acting Assistant Surgeon, United States Public Health Service*

This investigation was undertaken with the idea of establishing a simple chemical test for the detection of HCN in practical ship fumigation, first, as an aid in determining when a vessel is safe for habitation of its crew and workers after the fumigation procedure is completed, and, second, to establish the earliest moment when it would be safe for members of a fumigating crew to enter a hold or compartment of a vessel for the purpose of further ventilation and to search for rats.

As a criterion for these tests the following basic principles were laid down to which a chemical test should conform in order to be of practical value:

1. The test should be definite under all conditions, at or above the predetermined danger point to human life.

2. It should be such as can be applied without attendant danger to those making it.

3. The time factor of its reaction should be slow enough to permit of accurate computation with an ordinary watch in the hands of the usual personnel engaged in this work.

4. The test should be efficient within at least a 10 per cent of error as to time.

5. The varying atmospheric conditions at seaports should not materially affect the application of the test.

Both tests herein described depend upon change in color of filter paper which has been previously immersed in certain solutions.

BENZIDINE COPPER ACETATE

This test is certain proof of the presence of hydrocyanic acid gas in the air in all cases where no disturbing constituents can come into question (oxidizing gases such as chlorine and nitric acid) and is completed by dipping a strip of filter paper in a solution of benzidine and copper acetate and exposing the moist paper to the air of the compartment to be tested. In the presence of HCN the filter paper turns blue in periods varying from three to thirty seconds, depending upon the concentration of HCN. The test was originated by Sieverts and Hemsdorf and consists of two solutions, as follows:

(1) 2.86 gms copper acetate per liter of water.

(2) 475 c. c. saturated benzidine acetate solution with 525 c. c. of water.

Mix equal parts of (1) and (2) just before using. Slips of filter paper are dipped into this reagent and taken into the compartment to be tested in closed tubes. Upon exposure the paper will show from a very faint to an intense blue, indicating from 20 mgs. to 80 mgs. HCN per cubic meter.

A large number of tests were made with reagents, using many variations of the original formula. The most satisfactory was found to be that in which the original solutions were both diluted with equal parts of water. This gave a pale blue color on 10 seconds' exposure to 2.8 grams HCN per 1,000 cubic feet of air space. This modification of the original test was used in testing the holds and compartments of vessels during routine fumigation, and when used by those familiar with the test through laboratory experience it was found to be about 75 per cent efficient as compared with the results obtained in the usual method, that is, through the sense of smell, taste, and the exposure of white rats.

The benzidine copper acetate test requires that the test papers be read for a change in color after an exposure of from 7 to 10 seconds, which necessitates entering the compartment or hold before making the test (a procedure not without danger). An error of three seconds in reading the time factor would mean an error of 30 per cent or greater in the efficiency of the test. The results must be read while

the color is rapidly changing and the operator is in the presence of HCN. The color changes, in widely varying concentrations of HCN, are so slight that it requires considerable laboratory experience with known concentrations of HCN in order to make accurate determinations.

METHYL ORANGE-MERCURIC CHLORIDE MIXTURE

This test depends for its perception on a change of color of No. 40 Whatman filter paper which has been immersed in a mixture of methyl orange and mercuric chloride solutions, to which has been added a specified amount of glycerine, and then drained and hung up to dry. This paper, which is an orange color, turns pink upon exposure to HCN gas.

Experiments with this reagent were begun by using a concentration of solutions as specified by chemists of the R. & H. Chemical Co., which is as follows:

Solution No. 1. Mercuric chloride gms. 5 dissolved in 250 c. c. distilled water.
Solution No. 2. Methyl orange gms. 2.5 dissolved in 250 c. c. distilled water.

These solutions are mixed in the proportion of two parts mercuric chloride and one part methyl orange, and to the mixture is added 0.5 c. c. glycerine for every 15 c. c. of the mixture. The sheets of filter paper are immersed in this solution and hung up to dry in air which is free from any trace of acid, and when dry they are cut in strips ¼ inch wide and preserved in glass tubes protected from the light.

In conducting these tests a fairly gas-tight room containing 1,267 cubic feet of air space was used, having two outside windows which permitted the admittance of outside air so that the relative humidity of the room was approximately that of the outside. No artificial heat was used. Before being used, the filter papers were exposed to the outside air for a period of two hours or more with an approximate relative humidity of 74 per cent. The HCN was introduced in the liquid form containing 20 per cent CNCl which, being previously measured, was distributed in shallow glass dishes at various points in the room, and 10 minutes were allowed to elapse for complete diffusion before beginning the tests.

In order to determine the exact length of exposure necessary to complete the reactions, the writer remained in the test compartment, wearing a gas mask, when the concentration was 2.8 grams per 1,000 cubic feet or over, and without a mask when a lesser quantity of HCN was used. Two glass tubes, each containing a strip of the paper to be tested, were taken into the test room, one being opened after the 10-minute diffusion period and the paper exposed to the HCN, the other vial being kept stoppered for comparison. This method enabled the operator to make notes as to the time of the color changes during the test.

As previous experiments with white rats had established the fact that 3.35 grams of HCN per 1,000 cubic feet of air space was the mini-

mum lethal dose in a gas-tight compartment in an exposure of 12 hours, this concentration was taken as that in which a chemical test should give a definite reaction.

As the original test gave a reaction in 30 seconds, which was too fast for practical purposes in ship fumigation, a systemic series of tests was undertaken with lesser concentrations of the solutions, first diluting all reagents equally and then each reagent separately. Following this procedure a dilution of one-fourth the original concentration for methyl orange and mercuric chloride with double the original quantity of glycerine proved to give the most satisfactory results. This amended formula is given below, and the combined results of repeated tests are shown in the table.

Solution No. 1. Mercuric chloride, gms. 1.25; distilled water, c. c. 250.

Solution No. 2. Methyl orange, gms. 0.60; distilled water, c. c. 250.

Mix 10 c. c. of solution No. 1 with 5 c. c. of solution No. 2 and add 1 c. c. of glycerine.

Grams HCN per 1,000 cubic feet	Proportion of standard [1]	Duration of test in minutes				
		½	1	1½	2	3
6.7	1/10	Slight pink at edge	Faint pink	Definite pink	Red	Red.
3.35	1/20	No change	Slight pink at edge	Faint pink	Definite pink	Do.
1.675	1/40	do	No change	Brownish orange	Faint pink	Faint pink.
.8375	1/80	do	do	No change	Slight pink	Very faint pink.
.4187	1/160	do	do	do	No change	No change.
.2093	1/320	do	do	do	do	Do.

[1] The word "standard" indicates 2 ounces HCN per 1,000 cubic feet air space.

A study of this table shows that there is an approximate ratio between the concentration of HCN and the time of exposure. Two minutes' exposure to 1.67 grams of HCN per 1,000 cubic feet of air gives the same reaction as 1½ minutes' exposure to 3.35 grams, and a 1-minute exposure to 6.7 grams of HCN. It will also be seen that the minimum lethal concentration for white rats, namely, 3.35 grams per 1,000 cubic feet, is the lowest that produces a definite pink color within 2 minutes and that one-fourth that concentration (0.84 gram per 1,000 cubic feet) is the lowest concentration producing any change. In 2 minutes, 6.7 grams per 1,000 cubic feet, which is one-tenth the usual fumigation concentration, produces a distinct red.

From the test room in the laboratory the field of operations was transferred to vessels undergoing routine fumigation in New York Harbor, and a comparison was made with the live white rats which are used in testing holds. By means of a paper clip and string (a fishing line and reel is excellent), strips of the test paper were lowered into the holds for a 2-minute exposure, and upon withdrawal

of the paper, white rats were immediately lowered into the hold in an open cage and in the same locality in which the test paper had been exposed. A series of 55 comparative tests were made on 10 vessels. In 42 of the tests in which the test papers did not show a definite pink in 2 minutes, the white rats gave no symptoms of HCN poisoning in the 10-minute exposure period. In 10 of 13 tests in which the papers turned a definite pink in 2 minutes, the white rats showed the effect of HCN by agitation or prostration in from 1 to 5 minutes. In three tests in which the paper turned pink within the 2-minute exposure, the rats did not become agitated or exhibit signs of HCN poisoning in 10 minutes' exposure. These three tests were performed during a light mist, and excessive moisture probably accelerated the reaction of the test papers. Following all negative tests the holds were immediately entered by members of the fumigating crew in the usual manner and in no case was excessive concentration of gas encountered.

As most of the tests undertaken in these experiments were made from the practical standpoint, and considerable variation had been noted between various reagents, in filter papers, and in the moisture content of the papers, it was believed advisable to have the work checked by experienced chemists. Through the courtesy of Mr. L. M. White, of the Roessler & Hasslacher Chemical Co., two of the company's expert chemists, Mr. F. S. Pratt and Mr. Mark Walker, undertook, in the California laboratory of the company, to check the work and elaborate certain details. The result of this detailed check by experienced chemical research workers confirmed the writer's work as outlined, and in addition showed that 1 cubic centimeter of glycerin in the solution gave better constant results than the 0.5 cubic centimeter previously used. It also emphasized the importance of humidifying the test papers to a moisture content of between 7 and 8 per cent and maintaining them at this point until used. The effects of chloro-picrin, which in small amounts is an ingredient of zyklon–B, was tested by these same chemists and it was shown that a rather high concentration of 0.02 per cent of this gas, by weight in the air, did not affect the test paper upon exposure for six minutes to the gas.

SUMMARY

Two chemical tests for the detection of HCN were given practical trials in the fumigation of vessels and in the laboratory. One of these, the benzidine copper acetate test, is too rapid and too sensitive for practical purposes. The other, the methyl orange-mercuric chloride test has been modified to meet fumigating conditions.

The methyl orange-mercuric chloride test is very much slower than the benzidine copper acetate test and is sensitive to a concentration very much lower than the minimum lethal concentration of HCN.

It requires two minutes to complete its reaction, which allows for an error of a few seconds in reading the time factor without materially affecting the calculations. It is made with a comparatively dry filter paper which can be prepared in advance at a convenient place and which will keep under proper conditions of humidity for 30 days. The test can be accomplished by lowering a strip of the test paper into a hold by means of a clip and string, thus avoiding danger to the operator through exposure to HCN gas. The only apparatus necessary is a string and clip, a dark container with a supply of test papers, and two small glass vials, one carrying the immediate supply of test paper and one containing a single test paper for comparison. When desirable the test paper can be carried into a room or compartment in a small vial and then exposed for the desired length of time. In this test a 10 per cent error in noting the time of exposure would not materially affect the resultant conclusions.

Chloro-picrin reacting slowly with the test paper will not interfere with the practical operation of the test when fumigants containing this ingredient are used.

As the time exposure necessary to produce a reaction is shortened as the humidity increases, and vice versa, too much credence should not be placed in this test if used during rain or fog; otherwise a definite pink color at the end of two minutes' exposure indicates a dangerous concentration of HCN gas in the air.

It is apparent that this test depends upon a judgment of color for its accuracy, and considerable laboratory care is essential in preparing and maintaining the test papers at a fairly constant moisture content. For these reasons it is not believed that the test can completely replace the tests of smell, taste, and lachrymation as now used. (Under laboratory conditions, working with known quantities of HCN, it was established that the sense of smell could detect 0.25 cubic centimeter of liquid HCN per 1,000 cubic feet of air space, or approximately $\frac{1}{280}$ of the standard concentration used in ship fumigation.) However, this test is of value and can replace the use of white rats for testing holds, and, in conjunction with the sense of smell, taste, and lachrymation, is valuable as a further aid of safety in the final clearing of a vessel. Owing to the fairly high atmospheric humidity at most seaports an error in this test will probably be on the side of safety, which would result only in a slight delay in the clearing of vessels.

Practical work at the New York Quarantine Station has shown that test papers under atmospheric conditions of between 70 and 75 per cent relative humidity, and preserved in tightly stoppered bottles with air of the same humidity, will give good practical results for a period of two weeks. Under these conditions a majority of the quarantine stations should be able to prepare their own test paper

by using the wet and dry bulb method of ascertaining humidity or consulting the local United States Weather Bureau for data.

This test is of value and has been used at the New York Quarantine Station for the detection of leaking gas containers in storerooms and to establish the source of leakage from compartments undergoing fumigations.

DEATH RATES IN A GROUP OF INSURED PERSONS

Rates for Principal Causes of Death, February, 1928

The accompanying table is taken from the Statistical Bulletin for March, 1928, issued by the Metropolitan Life Insurance Co., and presents the mortality experience of the industrial insurance department of the company, by principal causes of death, for February, 1928, as compared with January and with February, 1927. The rates are based on a strength of approximately 18,000,000 insured persons in the United States and Canada.

A new low death rate for the month of February was established this year for this group of persons, the rate this year being 9.4 per 1,000 as compared with 9.6, which was recorded in both 1927 and 1921.

The Bulletin states:

The most important single factor in reducing last month's death rate to this new minimum was a drop in the mortality from tuberculosis to 89.5 per 100,000, as compared with 99.7 during the same month of 1927. Early indications point to a considerable reduction, for the year as a whole, from the previous minimal figure for tuberculosis which was established only last year. The year-to-date tuberculosis death rate among these policyholders for the first 12 weeks of 1928 was only 90.5 per 100,000, as compared with 97.7 for the same weeks of 1927. It should be borne in mind that the season of highest mortality from tuberculosis extends from January to May. If, therefore, the reduced death rate continues during March, April, and May, the end of 1928 will be almost sure to be signalized by still another new low record in the mortality from tuberculous disease.

Other diseases and causes of death to show improved mortality records over February of last year are typhoid fever, measles, scarlet fever, whooping cough, influenza, Bright's disease, conditions incidental to pregnancy and childbirth, suicide, and homicide.

On the other hand, the death rate in February was higher than last year for diphtheria, organic heart disease, and automobile fatalities. The rise in the diphtheria rate follows an increase in January over last year's figure for that month, and points strongly to a further rise in the diphtheria death rate this year. January and February are two of the months in which the diphtheria death rate runs much above the average.

The course of the automobile-accident death rate has been steadily upward for two decades, but no previous year has begun as badly as has 1928. Following a January death rate that had never been even approached by any previous figure for that month, no less than 228 policyholders were killed by automobiles in February, with a death rate of 15.8 per 100,000, which is higher by 37.4 per cent than the previous February maximum of 11.5 per 100,000, as recorded only last year.

Death rates (annual basis) for principal causes per 100,000, February, 1928, as compared with January and with February, 1927

[Industrial insurance department, Metropolitan Life Insurance Co.]

Causes of death	Death rate per 100,000 lives exposed [1]

COURT DECISIONS RELATING TO PUBLIC HEALTH

Presumption of violation of antinarcotic act because of absence of appropriate tax-paid stamps.—(United States Supreme Court; Casey *v.* United States; decided April 9, 1928.) The petitioner was convicted of violating the Harrison Antinarcotic Act, the charge being that he had purchased morphine, not in or from the original stamped package, at Seattle, within the jurisdiction of the court. The conviction was sustained by the circuit court of appeals. There was no testimony directly concerning the purchase, and the Government relied in part at least upon the presumption of a violation, created by section 1 of the antinarcotic act (act of December 17, 1914, 38 Stat. 785, as amended by the act of February 24, 1919, 40 Stat. 1130). The amended section 1 made the purchase, sale, etc., of narcotic drugs unlawful except in or from the original stamped package, and the absence of the required stamps from any of the said drugs "shall be prima facie evidence of a violation of this section by the person in whose possession same may be found." The petitioner argued that the presumption thus created did not and, consistently with the sixth amendment to the Federal Constitution, could not extend so far as to show a purchase within the district and thus bring the case within the jurisdiction of the trial court. The conviction, however, was affirmed by the Supreme Court, which said:

* * * But we are of opinion that upon the facts of this case the court was right. If the jury believed that the defendant, long established in Seattle, said

that he had not the drug but would, and shortly thereafter did, furnish it, the inference that he bought it in Seattle is strong, and it is reasonable to suppose that if attention had been called to the point the inference could have been made stronger still. * * *

With regard to the presumption of the purchase of a thing manifestly not produced by the possessor, there is a "rational connection between the fact proved and the ultimate fact presumed." (Luria *v.* United States, 231 U. S. 9, 25; Yee Hem *v.* United States, 268 U. S. 178, 183.) Furthermore there are presumptions that are not evidence in a proper sense but simply regulations of the burden of proof. (Greer *v.* United States, 245 U. S. 559.) The statute here talks of prima facie evidence, but it means only that the burden shall be upon the party found in possession to explain and justify it when accused of the crime that the statute creates. (4 Wigmore, Evidence, sec. 2494.) It is consistent with all the constitutional protections of accused men to throw on them the burden of proving facts peculiarly within their knowledge and hidden from discovery by the Government. (4 Wigmore, Evidence, sec. 2486.) In dealing with a poison not commonly used except upon a doctor's prescription easily proved, or for a debauch only possible by a breach of law, it seems reasonable to call on a person possessing it in a form that warrants suspicion to show that he obtained it in a mode permitted by the law. * * *

Garbage ordinance upheld.—(California Third District Court of Appeal; Ex parte Santos, 264 P. 281; decided January 28, 1928.) The petitioner had been convicted of unlawfully transporting garbage through the streets of the city of Sacramento in violation of a city ordinance. He sought his discharge by habeas corpus proceedings, alleging that section 1 of said ordinance was unconstitutional in that it deprived a private person of his property without due process of law. The ordinance, which regulated the collection and removal of garbage, provided, among other things, for the disposal of garbage and its transportation through the streets of the city only by duly authorized persons, and contained in section 1 the following definition:

Garbage, as the said word is made use of in this ordinance, consists of dead animals, of not more than 10 pounds weight each, and of every accumulation of animal, vegetable, and other matter that attend the preparation, consumption, decay or dealing in, or storage of, meats, fish, fowls, birds, fruits, or vegetables. The term "garbage" does not include dish water or waste water.

In denying the writ of habeas corpus, the district court of appeal stated:

We need consider only section 1 of the act in question, as all the other provisions are merely regulatory. * * *

All the authorities agree that the preservation of health of the inhabitants is one of the most important purposes of municipal governments. And the police power in this respect is coextensive with the necessities of the situation. That the collection and removal of garbage is one of these necessities requires no argument. Its disposal within a very limited period of time is of prime importance. Whether it is disposed of by cremation or by other methods is wholly immaterial. Its collection, transportation and removal from the limits of the

municipality are the fundamental purposes for the exercise of the police power regulating and requiring the same in order to protect the public health.

That the garbage in question may have some value as food for hogs does not in any wise limit the police power of municipalities. * * *

* * * In every city there is more or less ignorance, more or less willful disregard of all health laws, and much avarice which renders police regulations, such as we are here considering, absolutely indispensable, against which the so-called property right must yield to the general good. That such ordinances are not unconstitutional as violating any property rights is distinctly held by the United States Supreme Court in the case of California Reduction Co. *v.* Sanitary Reduction Co. (199 U. S. 306, 26 S. Ct. 100, 50 L. Ed. 204) and Gardner *v.* Michigan (199 U. S. 325, 26 S. Ct. 106, 50 L. Ed. 212).

* * * We find no modern authority which would justify our holding that section 1 of ordinance No. 146, fourth series, of the city of Sacramento, is invalid either as invading any property right or for any other reason suggested upon this hearing.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Sanitary Engineering Progress in the Middle West.—Wynkoop Kiersted. Proceedings Tenth Texas Water Works Short School, January, 1928. (Abstract by Jane H. Rider.)

The author reviews the changes in engineering practice which have occurred in the Middle West. He advocates the use of gumbo for a waterproofing material and describes the impounding reservoir constructed at Council Bluffs in 1882. The upstream face of the dam and the settling basins were lined with gumbo from the Missouri River bottoms, over which bricks were laid on edge in a 2-inch cushion of sand. After being in use 25–30 years, borings made into these linings showed the gumbo to be 18–28 inches thick. The courses of brick lining the dam were fairly straight, but those in the settling basin had been somewhat disarranged and had been patched with concrete.

Gumbo can also be used to fill the joints between concrete slabs, as an expansion joint in joining some types of concrete walls, and for packing the annular space around cast-iron pipe where it passes through a concrete wall.

Sedimentation and sterilization show the most marked improvements in water purification. The Kansas City water supply is given as an example that safe, potable water can be produced by sedimentation and chlorination alone. Filtration is entirely dependent upon the efficiency of settling basins. Changes in methods of sedimentation are described.

Sewage must be prepared for filtration or land treatment with the same thoroughness with which water is prepared for filtration. It is difficult to combine sedimentation, which is mechanical, with sludge digestion, which is biological, without mutual interference. The more thoroughly suspended solids are removed from sewage, the more easily it may be purified by natural processes on trickling filters or land without becoming offensive Solids should be caught in a preliminary basin and conveyed to a separate tank for digestion. Only organic matter in solution should be allowed on filters or applied to the land.

The Legislation of 1927 in Relation to Municipal Engineering.—J. B. R. Conder. *The Surveyor* (British), vol. 73, No. 1879, January 27, 1928, pp. 137–138. (Abstract by H. W. Streeter.)

Two (British) legislative acts, included under those of 1927, though passed in December, 1926, of special interest to sanitarians, were the housing (rural workers) act and the public health (smoke abatement) act. The former is designed to

promote the provision and improvement of housing accommodation for agricultural workers and persons of like economic status. It provides for the submission to the Minister of Health of schemes for reconstructing and improving houses or buildings and for subsidies or loans in respect to approved schemes, where the estimated cost of the dwelling, after execution of the proposed works, does not exceed £400, or the estimated cost of the works is less than £50 (or where the works will constitute an improvement to two or more dwellings for the provision of water, drainage, or other works for a joint benefit not less than £100).

The public health (smoke abatement) act extends the provisions of an act of 1875 relating to smoke nuisances. A chimney (other than that of a private dwelling) sending forth smoke in such quantity as to be a nuisance, is liable to be dealt with summarily, whether or not the smoke is black, the term "smoke" including soot, ash, grit, and gritty particles. The act also provides that the powers of an urban authority under the act of 1875 and of the London County Council are to extend to the making of by-laws requiring the provision of smoke prevention or reduction devices in new buildngs not private dwellings. The act became operative July 1, 1927.

Moscow Sewage Disposal.[1] Anon. *The Surveyor*, vol. 73, No. 1876, January 6, 1928, p. 2.

"The fifth report of the commission appointed to investigate the question of the disposal of the sewage of Moscow describes the method of disposal by land treatment which has been in operation since 1914. Separate sections are devoted to the engineering, agricultural, and chemical sides of the subject, and details are given of the results obtained on one of the two large farms used for the purpose.

"The area available for irrigation is about 2,000 acres, of which about 1,509 acres were in use in 1924. The soil is sand and clayey sand, and the area is divided into sections of 1 to 4 acres, to which the sewage is conveyed in the usual manner, by brick and earthen channels. Subdrains are arranged at a depth of 5 to 6 feet, and 35 feet apart. Various kinds of crops are cultivated, but the best results are obtained with hemp. This crop produces two to three times as much as under ordinary cultivation, and does not reduce the volume of sewage that can be treated per acre. The area occupied by this crop can be irrigated for 11 months in the year, as the work of cultivation does not take more than 4 weeks, and weeds are prevented from growing, as they are choked by the hemp.

"In spite of the fact that the river into which the final effluent is discharged has a flow of practically the same volume as the sewage effluent, the purification of the sewage is so satisfactory that the river water is not adversely affected."

Separate Sludge Digestion at Antigo, Wis. Anthony J. Fischer. Proceedings Tenth Texas Water Works Short School, January, 1928. (Abstract by Jane H. Rider.)

This plant consists of a two-section grit chamber, a bar screen, a clarifier with Dorr mechanism, a Dorrco pressure pump, a sludge digestion tank with heating coils and a Dorr digester mechanism, four sludge drying beds, a wet well, two siphon chambers, and two trickling filters. It was designed for an ultimate flow of 900,000 gallons per day and a contributing population of 10,000. The filter effluent discharges into a small creek of low flow.

The plant began operating in December, 1926. No ripe sludge was available for seeding, and so 5 feet of raw sewage was run into the digestion tank and the heating system was started. Raw sludge was then pumped into the tank daily. It was necessary to add milk of lime the first three months to adjust

---

[1] See also PUBLIC HEALTH REPORTS for Apr. 13, 1928, pp. 886 and 887.

the pH value; a sludge circulation system prevented the formation of a lime sludge at the bottom of the tank.

After 8 months' operation there was 4 feet of well-digested sludge in the tank averaging 8.9 per cent solids and 55.5 per cent ash. The supernatant liquid was clear and there was no scum. Fifty-nine per cent of raw solids are digested, giving an average of 11.5 cubic feet of gas per pound of volatile matter added. About 0.8 cubic foot of gas per capita per day is produced, which is burned under a Bryant boiler to heat the water used in the heating coils. Difficulties with gas collection were overcome by using a high separate seal dome, a well-insulated gas pipe, and a small gas holder.

Cyanide Waste Poured into Stream Poisons Livestock. A. H. Wieters. *Water Works Engineering*, vol. 81, No. 4, February 15, 1928, p. 204. (Abstract by H. E. Miller.)

Cattle died soon after drinking water from a small stream into which was discharged the effluent from an Imhoff tank of an intermittent sand filter disposal plant. Investigation disclosed that on this particular day a 600-gallon vat of electrolyte, which, among other salts, contained 2 pounds of sodium cyanide per gallon, had been dumped into the sewer by mistake. The question arises as to what effect small amounts of this substance will have upon the bacterial flora of sewage disposal systems.

Hydrants for Coach Yards and General Service and Methods for Supplying Water to Coaches. Report of the Committee on Water Service, A. R. E. A. *Railway Age*, vol. 84, No. 9B, March 7, 1928, pp. 560–D65–66. (Abstract by A. L. Dopmeyer.)

The report of the committee was divided into the following three sections: (1) Hydrants for coach yards and passenger station platforms where coaches are watered; (2) methods of supplying water to coaches from hydrants, including care and handling of hose, nozzles, and connections; (3) hydrants for general service such as ash pits, stock yards, small stations, and similar facilities.

Under the first section, the committee obtained information from representative railroads in all parts of the United States and the features of what are believed to be the most satisfactory type of hydrants for this purpose are listed in this article. It is concluded that the most suitable type of hydrants for this purpose is a quick-opening, self-draining, nonfreezing valve in a pit or box flush with the surface.

Under the second section it was concluded that the method of conveying drinking water from hydrants to coaches is satisfactory in practically every respect except the important one of sanitation, and that no method of protecting nozzles and hose ends yet devised has proved entirely satisfactory.

Under the third section, it was stated that some type of high top hydrant is preferred, which should be rugged in construction and have no parts which can be easily damaged or removed.

Sodium Aluminate as an Aid to Water Softening. Report of the Committee on Water Service, A. R. E. A. *Railway Age*, vol. 84, No. 9B March 7, 1928, pp. 560–D64–D65. (Abstract by A. L. Dopmeyer.)

In the addition of from 1 to 3 grains per gallon of aluminum or ferreous sulphate in the lime-soda treating process, it has been found that the aluminum hydrate or ferreous hydrate formed in the reaction weighs down the light particles of magnesium hydrate and causes them to settle more quickly, and also acts to free the softened water from the grain or so of calcium or magnesium carbonate, which is slow to come out of solution and causes "after-precipitation" and scale in the pipe lines.

However, if sodium aluminate is used instead of ferreous or aluminum sulphate, the results are usually found to be more speedy and complete. About 1½ grains of sodium aluminate per gallon of water are used.

Chlorination of Water Supplies in Assam. R. T. Sen. Proc. Assam Branch Brit. Med. Assoc. Annual Meeting, Silchar, March 1 and 2, 1926, pages 43–45. Abstract by Guy T. P. Tatham in *Bulletin of Hygiene*, vol. 2, No. 8, August, 1927, p. 649.

"Chlorination of the Sylhet water was started in July, 1922. Results were unsatisfactory at first and this was ascribed to improper dosage. With experience the defects were remedied, the total count was low and except for one occasion in February, 1925, lactose fermenters were absent from 20 c. c. In Silchar, chlorination was begun in May, 1924, and the results obtained were good from the start. Tables are given showing the bacterial improvement in the water supplied as compared with prechlorination figures. The author calls attention to certain disadvantages and difficulties in the use of chlorine to purify a water supply, viz, the unpleasant taste of free chlorine in the water, its possible injurious physiological effects, and the action on the water mains, also to the necessity for allowing adequate time of contact for the chlorine to exert its sterilizing effect. (If adequate time of contact is allowed at the waterworks it should not be necessary to give so high a dose that more than a trace of free chlorine—say 0.1 p. p. m. or less—passes into supply, and this will not give a taste of chlorine per se or injure the water mains. If a heavy dose is needed it is advisable to dechlorinate the water after allowing sufficient time of contact. Installation of a chlorinator (and a dechlorinator if necessary) by a firm of repute gets over the difficulties of effecting uniform dosage at known rate.)"

A Note on the Purification of Water from Rivers Polluted by Sisal Effluent. F. C. Kelly. Kenya M. J. 1926, v. 3, 212–15, Abstract by Guy T. P. Tatham in *Bulletin of Hygiene*, vol. 2, No. 8, August, 1927, p. 651.

"Samples of water were taken from and near a river flowing through three sisal estates in Kenya. The introduction of sisal waste at the factories results in marked deterioration of the quality of the river water, as judged by the oxygen absorbed and albuminoid nitrogen figures. The oxygen absorbed seems a very convenient test for the extent of pollution by sisal effluent, as the latter contains some as yet unidentified compound which exerts marked reducing properties. The water from two wells in the zone of pollution was examined. One, formed by a barrel sunk in the ground, was known to be polluted by human excreta, and the analytical results confirm this by the high figure for chlorides and the presence of nitrites and nitrates. The other, which is not subject to such pollution, shows a much better analysis. Fish can not live in water polluted by sisal effluent; frogs, however, are found in this well. The water from the river receives natural filtration on its way to the well and the conclusion is drawn that sisal pollution is removed by filtration."

Quality of the Surface Waters of New Jersey. W. D. Collins and C. S. Howard. Water Supply Paper 596–E, U. S. Geological Survey, Dept. of the Interior, 119 pages.

"The surface waters of New Jersey are one of the most valuable natural resources of the State. They are used for public water supplies of nearly all the larger cities, and they furnish the great quantities of water required for some of the leading industries. Where unpolluted, these waters are generally clear and contain only moderate quantities of dissolved mineral constituents. The waters in the southern part of the State are softer but more highly colored than the waters in the northern part."

Report of an Outbreak of Illness at Poplar Suspected to be Due to Local Pollution of the Water Supply. G. C. Hancock. *Bulletin of Hygiene*, vol. 2, No. 12, December, 1927, p. 982. (Abstract by C. R. Cox.)

An outbreak of illness characterized by very severe diarrhea of sudden onset, accompanied by fever, occurred in Poplar, England. Nervous symptoms manifested by convulsions or fits preceded the attacks in some cases. Generally speaking, the symptoms were very alarming at the onset, but subsided in 24 hours, leaving the patients weak.

The cases occurred in a relatively small area. Records of the analyses of samples of tap water examined by the Metropolitan Water Board of London indicated that locally the tap water was of an inferior quality. Further investigation disclosed the presence of a cross connection of a private water supply of a gas plant and the public mains. No check valves were used on this cross connection.

Use Watersheds for Recreation? W. L. Stevenson and H. E. Moses. *Water Works Engineering*, vol. 81, No. 2, January 18, 1928, pp. 81-82 and 109. (Abstract by Frank Raab.)

The article draws attention to the wide use made of watersheds for recreation, the danger which is involved therein, and the persistent demand by the public to be allowed the use of watersheds that furnish public supplies. New Jersey passed a law over the governor's veto permitting bathing in any fresh water of the State, provided no trespass is committed by such use. The article also discusses the rights of riparian owners of streams, etc. Pennsylvania establishes three zones on State forestry lands that serve as watersheds for public supplies. No camping is permitted "within 1 mile by stream above intake on a watershed"; within second mile leases are granted under stringent sanitary conditions. In the third zone, which comprises the remainder of the watershed, camping is permitted under stringent sanitary regulations. Another measure that is taken is the posting signs calling attention to the fact that the area is a watershed of a public supply and warning against any act that would jeopardize the purity of the supply.

Establishing Classifications of Public Water Supplies of West Virginia—First Official Classification. E. S. Tisdale. *Quarterly Bulletin* West Virginia State Department of Health, vol. 15, No. 1, January, 1928, pp. 15–19. (Abstract by H. B. Foote.)

The State sanitary engineering division has been at work for 12 years. The grading of the public water supplies is based upon yearly bacteriological records and knowledge obtained by periodic inspection by trained sanitary engineers. There are three classifications established:

(1) "Good," 82 of 154 supplies, or 53.2 per cent.
(2) "Doubtful," 44 of 154 supplies, or 28.6 per cent.
(3) "Bad," 28 of 154 supplies, or 18.2 per cent.

A large map is included which shows the location of each of the public supplies with its proper classification.

Can Filters Be Operated Satisfactorily at Variable Rates? Harry N. Jenks, *The American City*, vol. 38, No. 2, February, 1928, p. 128. (Abstract by W. L. Havens.)

Conclusions reached after actual operation of the Sacramento, Calif., filtration plant, with respect to effects of filter overloading, were as follows: (1) Provided overload rates are kept within proper limits, operation at variable rates has of itself no deleterious effect on the quality of the effluent; (2) variations in the rate of filtration to correspond to the curve of water consumption may result in reducing the size of storage reservoirs; (3) filter runs are shortened more by duration of overload rates than by the amount of such overload; (4) the permissible duration of overload decreases rapidly with increase in filtration rates above normal.

Water Purified by Electricity. Anon. *Water Works Engineering*, vol. 81, No. 3, February 1, 1928, p. 173. (Abstract by Chester Cohen.)

Description of a new method for purifying water accomplished through the electrolysis of the foreign matters in the water by the application of electric currents. The apparatus looks like a collapsed steam radiator and is composed of a group of connected cells through which the water passes successively, the electric voltage being stepped up in successive cells. The removal of waste matter takes place in the last cells mostly where the voltage is highest.

The apparatus is being used in Austria and Germany and experiments are under way to adapt the method to American waters.

Potassium Permanganate Purifies Water. John H. D. Blanke. *Water Works Engineering*, vol. 81, No. 6, March 14, 1928, p. 338.

"A deep well water supply system was contaminated with the seeping through of surface water. The supply water acquired a yellowish color, first still clear, and later opalescent and dull. As an immediate remedy potassium permanganate was used as a radical means. The success was surprising, since it was possible to break the organic iron combinations within a short time and to discolor the water at the same time. Potassium permanganate, if applied in such a quantity that the water still has a rose color after about two hours, always kills the *Bacterium coli* and nearly effects sterility even if the water is badly contaminated. *Wasser und Gas* of 1927, No. 18, pp. 933–937, states further that a small addition of chloride of lime of a high percentage, increases the bactericide effect."

Recent Developments in Water Treatment and Filtration. John R. Baylis. *Water Works*, vol. 67, No. 1, January, 1928, pp. 37–39. (Abstract by D. E. Kepner.)

Public opinion in years past against the so-called "doping" of water has to-day largely given way to indifference, leaving the water chemist unhampered in developing the types of treatment best suited to the particular waters at hand.

Among recent water treatment developments of note are the following: The prevention of corrosion and also the prevention of calcium carbonate deposition by proper chemical balance of the water; the use of pH tests for optimum coagulation control; the use of mechanical stirring devices for hastening chemical reactions and floc formation; the continuous removal of sludge, economical where the volume is over 0.05 per cent of the volume of water treated; the use of aeration to reduce the CO_2 content of water treated with aluminum sulphate; and the use of excess lime and recarbonation for treating hard waters.

"Experiments on the use of jets of water thrown into the filter sand while it is raised in washing, from a system of piping just above the sand surface, seem to work very well." An attempt, with partial success, has been made to develop a recording hydrogen ion machine, and work is also under way on devices for automatically recording the residual chlorine in water.

An Unusual Water Works. Willem Rudolfs. *Water Works*, vol. 67, No. 1, January, 1928, pp. 7–8. (Abstract by D. E. Kepner.)

At the Philips Glow Lamp Works, a water supply of about 2,000,000 gallons daily, having very little CO_2 and iron, and no manganese, is required for manufacturing use. The raw water, obtained from 42 driven wells, 60 feet apart and alternating 120 and 240 feet deep, contains 20 to 25 p. p. m. CO_2, 2 to 3 p. p. m. iron, and 0.3 to 0.4 p. p. m. manganese. The treatment plant comprises opposed jet aerators, a contact basin, filled with crushed lava, two settling tanks with detention of one hour, and two sand filters apparently arranged in series. $KMnO_4$ is added between the two filters to remove manganese. The effluent contains 2 to 4 p. p. m. CO_2, 0.1 p. p. m. iron, and no manganese. The filters are washed with air, as well as water. The neatness and attractive appearance of the plant are mentioned.

Zeolite Process of Water Softening. A. S. Behrman. *Water Works*, vol. 67, No. 1, January, 1928, pp. 26–28. (Abstract by D. E. Kepner.)

The recently developed gel-type zeolite has greater softening capacity and gives less trouble from disintegration than natural green sand and the older synthetic bare-exchange minerals. The gel type likewise permits greater rates of softening, and gives greater salt economy.

DEATHS DURING WEEK ENDED APRIL 14, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended April 14, 1928, and corresponding week of 1927. (From the Weekly Health Index, April 18, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended Apr. 14, 1928	Corresponding week, 1927
Policies in force	70, 634, 185	67, 347, 002
Number of death claims	16, 955	12, 654
Death claims per 1,000 policies in force, annual rate	12. 6	9. 8

Deaths from all causes in certain large cities of the United States during the week ended April 14, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, April 18, 1928, issued by the Bureau of the Census, Department of Commerce)

[1] Annual rate per 1,000 population.
[2] Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
[3] Deaths for week ended Friday, Apr. 13, 1928.
[4] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31; Baltimore, 15; Birmingham, 39; Dallas, 15; Fort Worth, 14; Houston, 25; Indianapolis, 11; Kansas City, Kans., 14; Knoxville, 15; Memphis, 38; Nashville, 30; New Orleans, 26; Richmond, 32; Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 100 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,575,000. The estimated population of the 95 cities reporting deaths is more than 30,900,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended April 7, 1928, and April 9, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
43 States	1,487	1,799	
100 cities	801	1,187	886
Measles:			
42 States	19,472	15,764	
100 cities	7,719	5,104	
Poliomyelitis:			
44 States	25	18	
Scarlet fever:			
43 States	4,390	5,469	
100 cities	1,652	2,341	1,347
Smallpox:			
42 States	1,261	770	
100 cities	108	155	118
Typhoid fever:			
43 States	186	204	
100 cities	27	47	46
Deaths reported			
Influenza and pneumonia:			
95 cities	1,472	1,078	
Smallpox:			
95 cities	0	0	

City reports for week ended April 7, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during non-epidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population July 1, 1926, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported
			Cases, estimated expectancy	Cases reported	Cases reported	Deaths reported

[1] Rabies (human): 1 case and 1 death at Boston, Mass.; 1 case and 1 death at Chicago, Ill.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended April 7, 1928, compared with those for a like period ended April 9, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1927 and 1928, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,050,000 in 1927 and 31,657,000 in 1928. The 95 cities reporting deaths had nearly 30,370,000 estimated population in 1927 and nearly 30,961,000 in 1928. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, March 4 to April 7, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

CHOLERA ON VESSEL

Steamship Hawaii Maru—At Singapore from Saigon and ports—April 3, 1928.—The steamship *Hawaii Maru* was reported April 3, 1928, at Singapore, Straits Settlements, from Saigon, French Indo-China, with cholera on board. The *Hawaii Maru* sailed March 20, from Nagasaki, and from Hong Kong March 23, 1928.

THE FAR EAST

Report for the week ended March 24, 1928.—The following report for the week ended March 24, 1928, was transmitted by the Eastern Bureau of the Health Section of the Secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Egypt.—Suez.
Aden Protectorate.—Aden.
India.—Bassein, Bombay, Rangoon.
Straits Settlements.—Singapore.

CHOLERA

India.—Bassein, Calcutta, Madras, Moulmein, Rangoon.
Siam.—Bangkok.
French Indo-China.—Saigon.
China.—Canton
Straits Settlements.—Singapore.

SMALLPOX

Ceylon.—Colombo.
Iraq.—Basra.
India.—Bombay, Calcutta, Madras, Moulmein Rangoon.
French India.—Pondicherry.
Dutch East Indies.—Banjermasin.
China.—Canton, Shanghai, Hong Kong.
Japan.—Shimonoseki.

Returns for the week ended March 24 were not received from the following ports:

Dutch East Indies.—Balikpapan, Samarinda.
Kwantung.—Port Arthur, Dairen.
Towns of the South Manchurian Railway Zone.

ARABIA

Aden Protectorate—Plague.—A total of 848 cases of plague with 549 deaths has been reported in the Aden Protectorate from the date of the outbreak, January 9, to March 20, 1928.

BOLIVIA

La Paz—Mortality Statistics—1927.—The Municipal Institute of Hygiene, Health, and Social Research of La Paz has reported deaths in the city of La Paz for the year 1927 as follows:

Disease	Deaths	Disease	Deaths
Bronchitis	178	Pneumonia	156
Dysentery	112	Tuberculosis	127
Gastroenteritis	215	Typhoid fever	54
Influenza	85	Typhus fever	34
Measles	294	Whooping cough	739
Smallpox	176	Other diseases	1,150

Estimated population, 110,000.

BRAZIL

Sao Paulo—Vital statistics, 1927.—The following table gives vital statistics for the city of Sao Paulo, Brazil, for the year 1927:

Population	934,185
Marriages	7,014
Births	27,708
Still-births	1,559
Deaths	14,106
Deaths under 1 year	4,621
Deaths from—	
Cancer	496
Cerebrospinal meningitis	11
Diphtheria	59
Dysentery (amebic)	46
Dysentery (bacillary)	58
Dysentery (other)	137
Influenza	241
Lethargic encephalitis	5
Deaths from—Continued.	
Leprosy	64
Measles	95
Plague	1
Poliomyelitis	1
Rabies	6
Scarlet fever	10
Suicides	84

Tetanus	51
Tuberculosis	1,023
Typhoid fever	185
Whooping cough	77
Other communicable diseases	203

CANADA

Provinces—Communicable diseases—Week ended March 31, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from five Provinces of Canada for the week ended March 31, 1928, as follows:

Disease	Nova Scotia	New Brunswick	Ontario	Manitoba	Alberta	Total
Influenza	41					41
Smallpox			20		7	27
Typhoid fever	1		6	4	6	17

Nova Scotia—Vital statistics—Year ended September 30, 1927.—The following data were taken from the annual report of the provincial health officer of Nova Scotia for the year ended September 30, 1927:

Population	523,837
Births	11,134
Births per 1,000 population	21.2
Deaths	6,259
Deaths per 1,000 population	11.9
Deaths of infants under 1 year	1,011
Infant mortality	90.8

Communicable diseases in Nova Scotia, year ended September 30, 1927

Disease	Cases	Deaths	Disease	Cases	Deaths
Cerebrospinal meningitis		11	Smallpox	[1] 1	
Diphtheria	200	25	Tuberculosis (pulmonary)		518
Measles	1,152	15	Tuberculosis (other forms)		99
Pneumonia		670	Typhoid fever	62	9
Scarlet fever	684	20	Whooping cough	351	47

[1] From vessel in harbor.

Quebec—Communicable diseases—Week ended April 7, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended April 7, 1928, as follows:

Disease	Cases	Disease	Cases
Chicken pox	21	Smallpox	15
Diphtheria	35	Tuberculosis	36
German measles	11	Typhoid fever	12
Measles	242	Whooping cough	7
Scarlet fever	86		

ECUADOR

Guayaquil—Plague—February, 1928.—During the month of February, 1928, six cases of plague with three deaths were reported at Guayaquil, Ecuador.

Plague-infected rats.—During the same period, 24,565 rats were examined at Guayaquil, and 31 rats were found plague infected.

Duran—Guayaquil—Smallpox.—During the period under report four cases of smallpox were reported at Duran (Eloy Alfaro) and five cases at Guayaquil.

ESTONIA

Communicable diseases—February, 1928.—During the month of February, 1928, communicable diseases were reported in the Republic of Estonia as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	13	Scarlet fever	380
Diphtheria	42	Tuberculosis	137
Measles	78	Typhoid fever	26

Population, estimated, 1,114,630.

GREAT BRITAIN

Birth, death, and infant mortality rates in England and Wales, 1841–1925.—The following figures are taken from the annual report of the Registrar General of England and Wales for the year 1926. They show the decrease in the birth, death, and infant mortality rates over a period of 85 years.

Period	Births per annum per 1,000 population	Deaths per annum per 1,000 population	Deaths of infants under 1 year per 1,000 births	Period	Births per annum per 1,000 population	Deaths per annum per 1,000 population	Deaths of infants under 1 year per 1,000 births
1841-1845	32.3	21.4	148	1886-1890	31.4	18.9	145
1846-1850	32.8	23.3	157	1891-1895	30.5	18.7	151
1851-1855	33.9	22.7	156	1896-1900	29.3	17.7	156
1856-1860	34.4	21.8	152	1901-1905	28.2	16.0	138
1861-1865	35.1	22.6	151	1906-1910	26.3	14.7	117
1866-1870	35.3	22.4	157	1911-1915	23.6	14.3	110
1871-1875	35.5	22.0	153	1916-1920	20.1	14.4	90
1876-1880	35.3	20.8	145	1921-1925	19.9	12.2	76
1881-1885	33.5	19.4	139				

LATVIA

Communicable diseases—February, 1928.—During the month of February, 1928, communicable diseases were reported in the Republic of Latvia as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	8	Puerperal fever	5
Diphtheria	44	Scarlet fever	228
Erysipelas	20	Smallpox	1
Influenza	35	Trachoma	42
Leprosy	2	Typhoid fever	65
Measles	320	Typhus fever	1
Mumps	42	Whooping cough	72

Population, estimated: 1,950,000.

NETHERLANDS

Communicable diseases—Year 1927—Average 1922-1926.—During the year 1927, cases of certain communicable diseases and deaths from these diseases were reported in the 11 provinces of the Netherlands as shown in the following table, which gives also the annual averages for the five-year period 1922 to 1926, inclusive. The figures for 1927 are provisional.

Disease	1927		Average 1922-1926	
	Cases	Deaths	Cases	Deaths
Cerebrospinal meningitis	108	46	111	63
Diphtheria	3,619	250	4,335	250
Dysentery	63	11	68	8
Lethargic encephalitis	101	64	[1] 80	[2] 53
Poliomyelitis	50	14	[2] 31	[2] 15
Scarlet fever	14,940	122	7,961	69
Smallpox	0	0	4	
Typhoid fever	776	87	1,218	148
Typhus fever	0	0	3	

[1] 3 years only. [2] 4 years only.

SALVADOR

Republic of Salvador—San Salvador—Mortality from malaria—Years 1925–1927.—During the period 1925 to 1927, inclusive, mortality from malaria was reported in the Republic of Salvador and the city of San Salvador, as follows:

Republic of Salvador			City of San Salvador		
Year	Population	Malaria deaths	Year	Population	Malaria deaths
1925	1,634,000	3,643	1925	86,000	172
1926	1,657,000	4,066	1926	87,000	209
1927	1,688,000	3,356	1927	88,000	186

SWITZERLAND

Lucerne (Canton)—Communicable diseases—January-February, 1928.—Communicable diseases were reported in the Canton of Lucerne, Switzerland, during the months of January and February, 1928, as follows:

Disease	Cases		Disease	Cases	
	January, 1928	February, 1928		January, 1928	February, 1928
Cerebrospinal meningitis	1		Measles	46	39
Diphtheria	7	18	Scarlet fever	10	13
Influenza		5	Typhoid fever		1
Lethargic encephalitis		8	Whooping cough	26	21

Population: 45,700.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg. Gen. R. C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

VOL. 43 MAY 4, 1928 NO. 18

THE CAUSES OF ILLNESS AT DIFFERENT AGES[1]

Hagerstown Morbidity Studies No. VII[2]

By EDGAR SYDENSTRICKER, *Statistician, United States Public Health Service*

In this paper the general results of the Hagerstown morbidity study which relate to the causes of illness at different ages are summarized briefly. The tables and graphs, it is believed, present the principal findings with respect to this phase of the inquiry, but a word or two of explanation may assist the reader who is not conversant with the previous reports in this series.

The record of illness was obtained from a responsible informant (usually the housewife) in each household canvassed by a trained field assistant and was supplemented by diagnoses from attending physicians in practically all cases where medical care was given, and by records of school attendance and of clinics. Forty-six per cent of the illnesses were attended by physicians; if we omit "colds" and minor digestive illnesses, 65 per cent were so attended and were diagnosed by medical practitioners. Two-thirds of the population studied were observed at intervals of 6 to 8 weeks for at least 24 of the 28 months, which was the duration of the study. Less than 1 per cent of the illnesses had to be classified as "ill-defined and unknown." For further details as to the scope and method of the study, definition of illness, etc., reference is made to the first paper of this series.

In those cases in which more than one cause was recorded, recourse was had to the practice followed in the classification of the causes of death, namely, to assign only one cause to each illness. This arbitrary procedure does not, however, affect a very large proportion

---

[1] From the office of statistical investigations, U. S. Public Health Service.

VI. The Illness Rate Among Males and Females. Pub. Health Rep., vol. 42, No. 30, July 29, 1927. Reprint No. 1172.

of the cases. Of the 17,847 illnesses observed, only 3.7 per cent had more than one cause or condition recorded. The procedure in classifying these cases according to a "primary" cause was as follows:

(1) The *first* cause in order of occurrence, applied largely to acute conditions with common complications, such as influenza and pneumonia, or measles and otitis media.

(2) *Acute* conditions ordinarily were given preference over an attack of some chronic condition. Thus, in case of grippe and chronic rheumatism, the grippe was considered primary.

(3) The condition or disease *most specifically associated with the period of sickness* was preferred over a minor condition which preceded or accompanied it. For example, in tooth abscess and rheumatism, the latter was made primary. When it was difficult to determine the factual basis, the more serious condition was chosen.

(4) The *more specific* cause was given preference over a statement of a symptom.

(5) When none of the above rules could be applied, and the history of the individual gave no basis for decision, the condition mentioned first by the informant was made primary. The number of such cases was very small.

The size of the experience in the different age groups employed is shown in the following table:

TABLE 1.—*Number of white persons observed for the incidence of illness in Hagerstown, Md., December 1, 1921–March 31, 1924, expressed in terms of "years of life observed," and classified by age*

Age in years	Number of years of life observed	Age in years	Number of years of life observed
All ages [1]	16,517	15-24	2,526
0-4	1,777	25-44	4,643
5-9	2,105	45-64	2,575
10-14	1,713	65 and over	810

[1] Includes 368 years of life observed in persons whose ages were not exactly enough known for classification according to the groupings used.

With respect to the term "years of life observed," it should be stated that of necessity certain individuals and families were observed for less than the entire period of the study. In order, therefore, to state the morbidity results in terms of annual incidence rates it was necessary to resort to the familiar device of expressing the population as the number of "year-persons," or the number of "years of exposure," or, to state it more precisely, perhaps, the number of "years of life observed" within each age category. No age group includes less than 810 such years of observation.

Since our immediate purpose is to indicate the general nature of illness, rather than the incidence of specific diseases, at different ages,

the illnesses have been grouped into only 18 classes, with the exception of tonsillectomies, adenoidectomies, and other operations on the throat or nasal fossae which are shown separately. The scheme of classification used was the International List of Causes of Death, 1920 revision. This list, unsuitable as it is for any scientific classification, because of its illogical combination of anatomical, etiological, pathological, epidemiological, and other bases, is resorted to because it is the only classification generally used. Some departures, dictated by considerations which we believe will be apparent to anyone more interested in the causes of illness than in a mere scheme of classification, were made from it; but in the tables presented, the International List numbers are carried for definitive purposes.

The data so classified are presented in Table 2, together with the "years of life observed" within each age group. In Table 3 are given the annual rates, based upon the figures in Table 2.

TABLE 2.—*Number of illnesses, by age groups, in which a specified disease or condition was the sole or primary cause in a group of white persons observed in Hagerstown, Md., December 1, 1921–March 31, 1924*

Disease or condition (numbers in parentheses refer to those given in the International List of Causes of Death, 1920)	Number of illnesses in which the specified disease or condition was the sole or primary cause							
	All ages [1]	Age group

Ill-defined and unknown	1.67	.55	.74	.59	.87	1.11	1.26

The relative importance of the general groups of kinds of causes in different age periods is shown in the percentages given in Table 4. The predominance of respiratory causes, which account for over half of the illnesses in every age period, is the most striking feature of our findings. The relative importance of other groups of causes varies considerably from age to age, so that, comparing one age period with

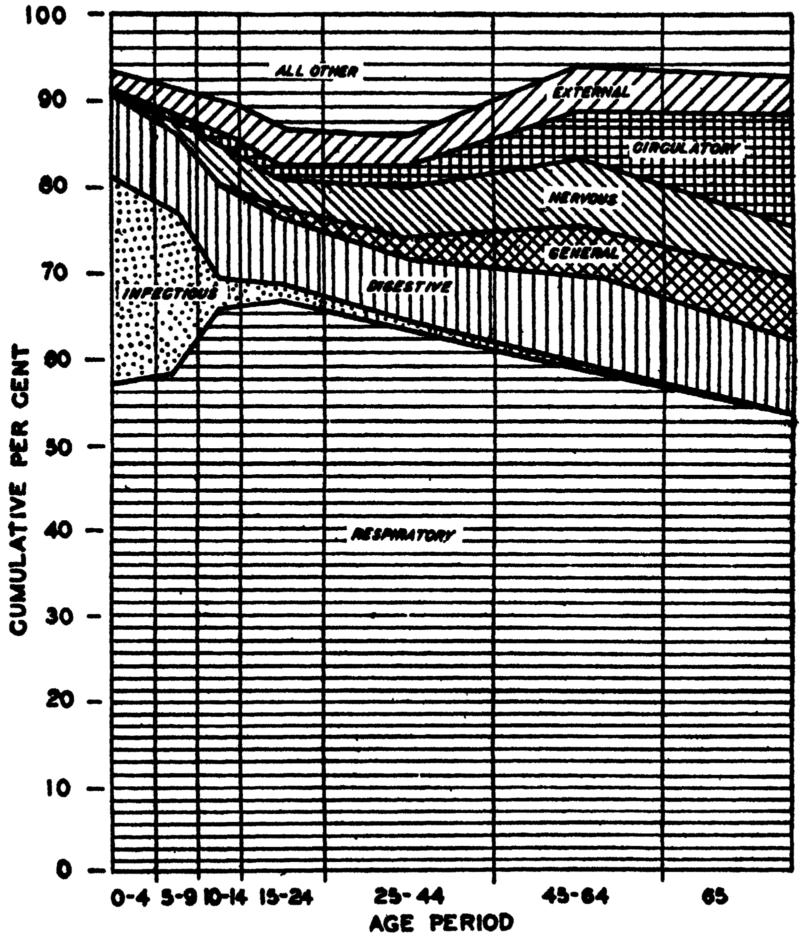

FIG 1—The relative importance of the major groups of diseases as causes of illness in different periods of life in a white population group in Hagerstown, Md, Dec 1, 1921-Mar 31, 1924 In the diagram the total illness rate at any age is 100 per cent

another, there is a marked difference in the kinds and causes of sickness. In Fig. 1 an attempt has been made to depict these contrasts.

Each period of life is characterized by its own distribution of the causes of illness. In childhood, illness other than respiratory is caused chiefly by communicable diseases, diseases and conditions of the skin, ears, eyes, and teeth, and nervous and digestive disorders; in old age

illness other than respiratory is caused by the organic group of diseases and conditions—those of the circulatory system, nervous system, and kidneys. Illnesses resulting from all of these causes are at their lowest level in adolescence and young adult ages. The only *major* cause which results in a higher rate of disability in young adult life than at any other age is the puerperal condition, and this, of course,

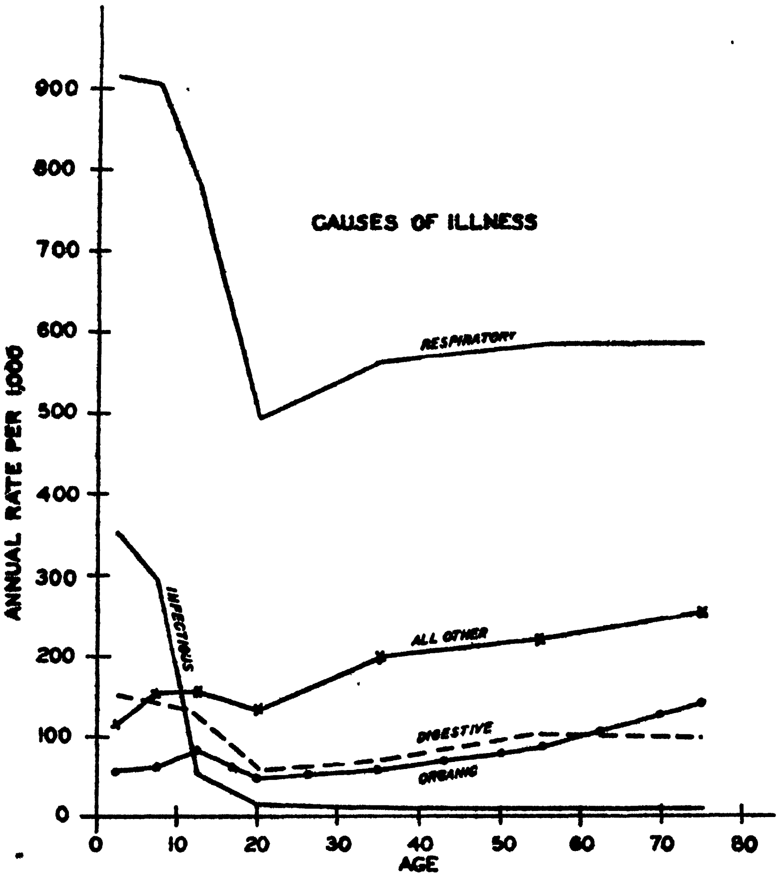

FIG. 2.—Causes of illness at different ages in a white population group in Hagerstown, Md., Dec. 1, 1921-Mar. 31, 1924. Under "infectious" diseases are included the "epidemic, endemic, and infectious diseases," and under "organic" the following. Diseases of the eyes, ears, circulatory system, teeth and gums, kidney, and genito-urinary system

relates to females only. Certain specific causes of illness do have their highest incidence in the young adult period of life, such as venereal diseases, typhoid fever, and pulmonary tuberculosis except under conditions of special strain or hazard. But, by and large, this is the age most free from illness from the great majority of causes.

Since the diagram we have been discussing (fig. 1) exhibits only the relative importance of the causes of illness at different ages, we

have plotted graphs in Figures 2 and 3 to show the actual variations in the illness rates from the major groups of causes. The importance of respiratory diseases and conditions as causes of illness is again emphasized; but their great height in childhood, their lowest level in adolescent and young adult periods (15–24 years), and their gradual rise with the advance of age are quite striking. They characterize illness in both extremes of life more than any other general disease group; although, with the exception of infectious diseases, circulatory

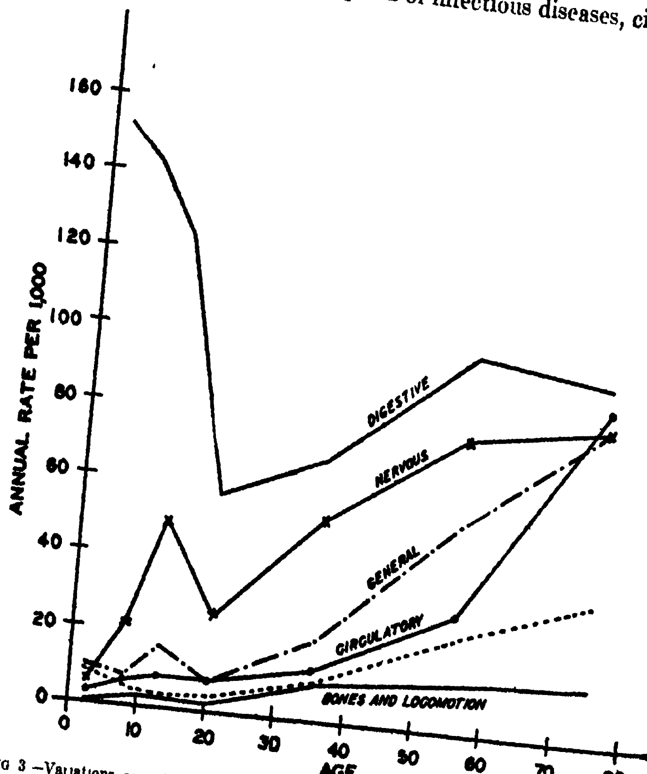

FIG 3.—Variations, according to age, of certain groups of diseases which were primary causes of illness in a white population group in Hagerstown, Md., Dec. 1, 1921–Mar. 31, 1924. The dotted line represents "diseases of the kidney and annexa."

diseases, and diseases of the bones and of "organs of locomotion"—which so clumsily describes diseases that affect certain muscles—nearly all of the major groups of causes of illness tend to appear among the very young and among the old.

In contrast to the organic troubles which so definitely begin to be manifested in middle life and which characterize old age, are the infections and the diseases and conditions affecting the skin, teeth, eyes, and ears (fig. 4) that occur with greatest frequency in childhood.

With this general view of the causes of illness at different ages, it is purposed to present in more detail in the next paper the age variations in the incidence of a number of specific diseases and conditions in so far as they were manifested in illness in the Hagerstown group.

ACKNOWLEDGMENTS

The continuous field observations upon which the foregoing report is based were made by the following assistants: F. Ruth Phillips,

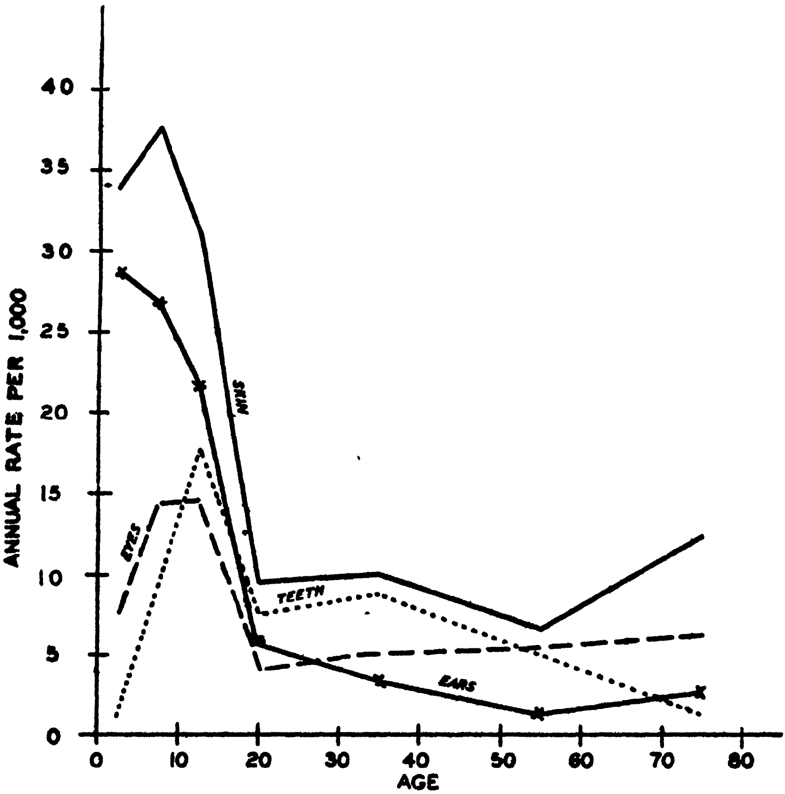

FIG 4.—Incidence, according to age, of diseases and conditions of the skin, teeth, eyes, and ears in a white population group in Hagerstown, Md., Dec. 1, 1921–Mar. 31, 1924

Mrs. Mary King Phillips, Louise Simmons, Mrs. Clara Bell Ledford, Clarice Buhrman, and Mrs. Alcesta Owen, under the immediate supervision of Passed Asst. Surg. R. B. Norment, jr., Acting Asst. Surg. A. S. Gray, and later, Surg. C. V. Akin.

In the analysis of the data I am especially indebted to Miss Phillips and to Associate Statistician S. D. Collins and Assistant Statistician Dorothy G. Wiehl, and other members of the statistical staff, as well as to several officers of the Public Health Service for constant advice on medical points.

WHOLE-TIME COUNTY HEALTH OFFICERS, 1928

The following directory has been compiled from data furnished as of January 1, 1928, by State health officers. Similar directories for the years 1922 to 1927, inclusive, have been published in the PUBLIC HEALTH REPORTS. The directory for 1927 was issued as Reprint No. 1164.

In the questionnaire sent for the purpose of obtaining the necessary information, a "whole-time" county health officer was defined as "one who does not engage in the practice of medicine or in any other business, but devotes all his time to official duties."

Directories of State health departments have been published annually by the Public Health Service for the years 1912 to 1927, inclusive. The directory for 1927 was issued as Reprint No. 1188 from the PUBLIC HEALTH REPORTS.

Directories of city health officers have been published annually for the years 1916 to 1927, inclusive, the directory for 1927 being Reprint No. 1177.

Directories of State and city health officers for 1928 will be published later.

UNIVERSITY OF MICHIGAN SUMMER COURSES IN PUBLIC HEALTH

The University of Michigan offers two groups of courses in hygiene and public health during the coming summer session, which is to be held this year from June 25 to August 3.

The public health training courses will include the following subjects:

(*a*) General hygiene and public health.
(*b*) Child hygiene.
(*c*) School hygiene.
(*d*) Methods and materials in health education.
(*e*) Communicable diseases and epidemiology.
(*f*) Nutrition.
(*g*) Public health nursing.
(*h*) Mental hygiene and psychiatry.
(*i*) Vital statistics.
(*j*) Tuberculosis.
(*k*) Organization and administration of health education.

Many other courses will be offered which will be of interest and value to public health workers. These will include biology, chemistry, bacteriology, sociology, education, psychology, and medicine.

The course in tuberculosis should prove to be of particular interest to all persons engaged in antituberculosis work. The nursing, medicosocial, and community aspects of tuberculosis will be considered. The course will be conducted by several of our leading specialists in tuberculosis.

In addition to the above, a special Public Health Institute will be conducted on Friday and Saturday of each week during the summer

session. This institute is arranged primarily for those who are engaged in public health activities and find it impossible to leave their work for the six weeks of the regular summer session, but can arrange to get away from their labors for two days each week. It consists of six class periods on each Friday and Saturday for six weeks—making a total of 72 class periods. The class periods are arranged to cover the various fields of public health.

PUBLIC HEALTH ENGINEERING ABSTRACTS

First Principles in Sewage Disposal. F. C. Temple. *The Surveyor*, vol. 73, No. 1883, February 24, 1928, p. 259. (Abstract by H. W. Streeter.)

A reply to discussions of Mr. Temple's paper, presented at the Public Works, Roads, and Transport Congress at London in November, 1927. Mr. Temple points out the differences existing in the conditions affecting the operation of storm-water tanks in tropical countries, as compared with more temperate climates. In the former case, tanks may be made smaller, but must be filled with clean water between rainy periods in order to provide sufficient capacity for extremely heavy flushings of solid matter accompanying the first tropical rains following long droughts. As regards damage caused by trade wastes, he draws a parallel to aerial nuisances, which are controlled by law. He discusses the standardization of terms defining the relative strength of sewage, noting that an Indian "strong" sewage is stronger than any British sewage, which, in turn, is stronger than American sewage.

Methods Used by Oil Company Stop Pollution of Streams. Charles W. Geiger. *Water Works Engineering*, vol. 81, No. 2, January 18, 1928, p. 90. (Abstract by Frank Raab.)

At the El Segundo refinery, the Standard Oil Co. of California pumps about 20,000,000 gallons of salt water daily from the ocean. The water is used for cooling purposes in the refining of oil. In its way through the refinery the water picks up a certain amount of oil from leaks, spills, etc. The oil is about one-tenth of 1 per cent of the volume of water used. This oil is removed from the water before the latter is returned to the ocean. The article describes the method used in separating the oil and water by passing it through a tank or series of tanks or compartments and over skimming baffles in an action which keeps the water and oil moving toward the surface, thus assisting and accelerating the movement of the oil to the surface where it is pumped off. The above plant removes all traces of oil from the water.

Deep-Pit Sludge Digestion at Indianapolis Sewage Works. C. K. Calvert. *Engineering News-Record*, vol. 100, No. 6, February 9, 1928, pp. 230–231. (Abstract by C. H. Kibbey.)

Sludge containing 7.72 and 1.12 per cent solids, respectively, is pumped to digestion pits. Pits are about 300 feet square, with a depth of 7 to 10 feet. The nature of the soil beneath the pits permits water to escape to such extent that it is only occasionally necessary to remove any quantity of free water, although skimming boxes are provided for the removal of liquor at any depth.

No chemical or temperature control is provided. A pit receives sludge until it is full, and the flow is then diverted to another pit until the level of the sludge in the first pit is lowered by filtration into the ground. This brings about a series of intermittent fillings and effects some seeding. During filling periods, pits become more acid, especially in cold water.

Primary sludge enters the pit at a pH of about 6.8 and the activated sludge at 7.3. Under normal filling conditions the mixed sludge seldom drops during digestion below 6.8, and, on standing, without the addition of fresh sludge, goes to 7.8 and 8 in a short time. Above figures indicate conditions under which digestion usually takes place, but hard and fast reaction and time figures can not be given. Relative amounts of fresh and digested sludge and the temperature govern the rate of reaction change.

A tabulation showing figures obtained in taking stock of sludge in the various pits is given. The large reduction in volume is attributed to the nature of the soil underlying the pits and the extent of digestion of solids to the long period of time involved, although the method of filling produces a mixture of some very old and some very fresh sludge in each pit. The mixture has never drained to less than 80 per cent of moisture, and for the most part a moisture content of about 85 per cent obtains.

The author believes that, as the proportion of activated sludge increases, satisfactory draining becomes more difficult and that drying beds will be required to put sludge in a condition to be handled. The present use of sludge by growers has not solved the problem of disposal, but its use may be developed and extended as growers become familiar with its advantages.

Water Supply, Sewage Treatment, and Refuse Disposal in 1927. H. B. Cleveland. Public Works, vol. 59, No. 1 January, 1928, pp. 14–18. (Abstract by R. J. Faust.)

Sewage treatment.—The year 1927 has marked a decided increase in interest on the part of the general public in sewage treatment in eliminating stream pollution. This resulted in the enactment of State laws providing for joint sewer districts, for assessment of sewage-disposal costs as a utility, and for legislative and departmental investigation of stream pollution problems.

Major plants completed, under construction, or planned are as follows: North Side, West Side, and Southwest Side plants at Chicago; a $20,000,000 Imhoff tank plant for Detroit has been recommended and approved; a Metropolitan Drainage Commission has been appointed to work out plans for joint sewage treatment for St. Paul and Minneapolis. An increasing favor toward separate sludge digestion is noted for smaller plants.

The principal studies on research on which conclusions were reached are as follows: (1) Hydrogen sulphide production, with particular reference to the effects of unfiltered sea water; (2) the effect of comparatively small amounts of chlorides (as found in sea water) is slight; (3) sewage screenings contain comparatively large quantities of carbonaceous materials, but may be digested rapidly under proper conditions; (4) all fats may eventually be digested, but not necessarily within economic limits; (5) at the optimum temperature of 80° F., the permissible daily addition of fresh solids to ripe sludge may be increased to 3.25 per cent, as against 2 per cent at 70° F.; (6) The average time of digestion in separate sludge digestion taken at Plainfield, N. J., was 40 days at a temperature of 67°–68° F., average pH value was 7.3; (7) more than 75 substances were tried as possible filter fly controls, but none proved satisfactory.

Treatment of London Sewage. Anon. *The Surveyor*, vol. 73, No. 1883, February 24, 1928, p. 271. (Abstract by H. W. Streeter.)

The London County Council Main Drainage Committee have submitted proposals for the installation at the northern outfall works, at Barking, of a plant for the treatment of sewage by the activated sludge process, estimated to cost about $1,250,000. The plant is intended to deal with 5 to 10 m. g. d. out of a total of 258 m. g. d. After experience of the proposed installation, further works are contemplated. The average daily quantity of effluent discharged from the

northern outfall is 164 m. g. d., and from the southern outfall, 94 m. g. d. Dilution is provided mainly by the Thames and its tributaries, only a small volume of tidal waters being considered as available for this purpose. Other effects of the tide are, however, favorable, including (*a*) the spreading of polluted water over a long stretch of purer water, (*b*) facilitation of atmospheric reaeration of the water caused by its movement, and (*c*) the prevention of formation of permanent undisturbed fermenting mud banks. Further natural factors modifying aeration are area of water surface, depth, temperature, air humidity, salinity, wind, etc.

Investigation and Research. Anon. Thirteenth Annual Report of the Bureau of Sewage Disposal, City of Schenectady, New York, 1927, pp. 9–10. (Abstract by W. L. Havens.)

During the winter of 1926–27 an investigation was carried out to ascertain the effect of chlorination of the raw sewage, prior to settling-tank treatment. Chlorine was added at rates varying from 6 to 2 p. p. m., with the result that no residual chlorine was found in the tanks during the study. No bacterial reduction in the tank effluent was obtained and no deleterious effect was produced by gas treatment. Odor conditions were excellent about the plant during the entire summer; and during cooler weather, rates of application of about 1 p. p. m. produced the desired results. Liming of the Imhoff tanks was practiced, with the intention of starting pH control. In addition, a river survey was begun in order to determine the necessity of formulating plans for the treatment of the balance of the sewage flow of the city which is now entering the river untreated.

Rivers Pollution Prevention Work of the West Riding Board. Anon. *The Surveyor*, vol. 73, No. 1883, February 24, 1928, p. 260. (Abstract by H. W. Streeter.)

The remarkable improvement effected during the past 30 years in the condition of streams in the West Riding of Yorkshire as the result of the work of the West Riding Rivers Board is demonstrated in a special report by the Board's chief inspector, Dr. H. M. Wilson.

The streams, with tributaries, under survey of the board had a total length of over 2,000 miles, including some clean rivers, and others in various states of pollution. There are now 427 sewage works in the board's area, as compared with 167 in 1896. Many works, however, have been abolished, with the process of concentration still going on.

Only those who remember the condition of the streams 20 or 30 years ago, concludes Doctor Wilson, and those who realize the great addition to the total volume of sewage since then, could have any conception of the foul state in which the streams would have been at present had it not been for the work of the board. Pollution of the cleaner streams has been dealt with at an early stage, preventing deterioration already begun.

The Ozone Fallacy in Garage Ventilation. Carroll M. Salls. *Journal of Industrial Hygiene*, vol. 9, No. 12, December, 1927, pp. 503–511. (Abstract by Leonard Greenburg.)

Doctor Salls presents a discussion of the literature concerned with the reaction of carbon monoxide and ozone, and from this discussion one must conclude that there is great variance in the literature concerned with this reaction.

The experimental studies presented are analyses of the atmosphere from a gassing chamber in which carbon monoxide is mixed with ozone at room temperature. The atmosphere was sampled from the beginning of the mixture of the gases through a period 140 minutes thereafter. The carbon monoxide determinations were made by means of the Sayers-Yant method, using defibrinated steer's blood as a blood reagent. Three samples of the atmosphere were obtained prior to starting the ozonator, the three samples yielding the following results in chronological order: 13, 9, and 7 parts of carbon monoxide. After allowing the ozonator to

operate for about 20 minutes a sample was taken which yielded somewhat less than 5 parts of carbon monoxide. Subsequent samples were taken to the end of 140 minutes. When these samples were plotted against time, they fell on a fairly uniform curve which appears to be the curve of absorption of gas by the chamber walls and leakage through them. The starting of the ozonator appears to have altered the shape of the curve in no way.

Doctor Salls concludes that this study indicated no evidence of an appreciable action of the ozone on the carbon monoxide.

Preventing Excessive Smoke. J. F. Bjorkholm. *Railway Age*, vol. 84, No. 6, February 11, 1928, pp. 357–359. (Abstract by Leonard Greenburg.)

One of the most important discriminations in the field of smoke abatement, so far as railroading is concerned, is the differentiation between smoke prevention and "smoke painting" or whitewashing. The latter is merely a method of decoloring smoke by means of wet steam or vapor, whereas the former, the correct method, requires improved combustion. The author further points out that smoke burning or smoke combustion are misnomers, because smoke already formed ordinarily can not be burned or consumed. The greatest difficulty in avoiding smoke is usually on switch or transfer engines, owing to the nature of their work, and on road engines starting out from their terminal. Here it is necessary to rely on the blower and "smoke burner," by means of which additional air is admitted to the fire box, this air serving to prevent the formation of smoke. When the steam jets are used in the fire box without inducing the flow of additional air into the fire box, the steam jets merely serve to paint the smoke and not to prevent it.

In addition to this generous supply of air, a sufficiently high fire-box temperature is necessary to prevent smoke formation. And, lastly, it is to be pointed out that the proper method of firing has considerable influence on smoke formation. Only a sufficient amount of fuel should be placed in the fire box at each firing to insure proper combustion.

Atmospheric Diffusion of Paris Smokes. Kohn-Abrest. Compt. rend. 185, 617–20 (1927). (Abstract by L. W. Riggs in *Chemical Abstracts*, vol. 22, No. 3, February 10, 1928, p. 473.)

"Samples of air taken at the base and at elevations of 57, 115, and 288 m. of the Eiffel Tower were analyzed. The quantity of CO_2 was about the same except at 288 m., where it was larger than at any of the lower levels. CO was absent at the base and at 288 m ; it was largest in amount at 115 m."

A New Larvicide for Mosquitoes. Robert Matheson and G. H. Hinman. *American Journal of Hygiene*, vol. 8, No. 2, March, 1928, pp. 293–296. (Abstract by L. L. Williams, jr.)

The authors experimented with chemically pure borax, with crystalline and calcined sodium borate, and with commercial borax. The latter was found to be as efficient as any. After experimenting with various concentrations, the authors conclude that ordinary borax in the concentration of 1.5 grams per liter of water proved an efficient larvicide for mosquito larvæ. This retains its action for long periods of time in wooden pails. Borax did not stop egg laying and hatching, but in no case did the young larvæ live for more than two days.

They quote reports that borax pools do not produce mosquitoes and that, in a borax country, this substance is not absorbed into the ground, but crystallizes on evaporation of the water and is ready for the next rain. The authors suggest that there is a field of usefulness for borax as a larvicide in such places as fire barrels, etc.

Water Supply, Sewage Treatment, and Refuse Disposal in 1927. H. B. Cleveland. *Public Works*, vol. 59, No. 1, January, 1928, pp. 14–18. (Abstract by R. J. Faust.)

DEATHS DURING WEEK ENDED APRIL 21, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended April 21, 1928, and corresponding week of 1927. (From the Weekly Health Index, April 25, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended Apr. 21, 1928	Corresponding week, 1927
Policies in force	70, 998, 155	67, 421, 189
Number of death claims	15, 838	13, 589
Death claims per 1,000 policies in force, annual rate	11. 7	10. 5

Deaths from all causes in certain large cities of the United States during the week ended April 21, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, April 25, 1928, issued by the Bureau of the Census, Department of Commerce)

[1] 61 of these cases are delayed reports for year 1927.

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 100 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregated population of more than 31,400,000. The estimated population of the 94 cities reporting deaths is more than 30,700,000. The estimated

expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended April 14, 1928, and April 16, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
43 States	1,440	1,724	
100 cities	867	1,037	883
Measles.			
42 States	17,668	15,173	
100 cities	8,112	4,547	
Poliomyelitis:			
43 States	21	13	
Scarlet fever:			
43 States	4,191	5,185	
100 cities	1,365	2,296	1,324
Smallpox:			
43 States	1,060	881	
100 cities	123	143	133
Typhoid fever.			
43 States	161	278	
100 cities	33	47	48
Deaths reported			
Influenza and pneumonia:			
94 cities	1,390	999	
Smallpox:			
94 cities	0	0	

City reports for week ended April 14, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during non-epidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population, July 1, 1926, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended April 14, 1928, compared with those for a like period ended April 16, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1927 and 1928, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,050,000 in 1927 and 31,657,000 in 1928. The 95 cities reporting deaths had nearly 30,370,000 estimated population in 1927 and nearly 30,961,000 in 1928. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, March 11 to April 14, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

THE FAR EAST

Report for the week ended March 31, 1928.—The following report for the week ended March 31, 1928, was transmitted by the Eastern Bureau of the Health Section of the Secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Egypt.—Suez.
Aden Protectorate.—Aden.
India.—Bassein, Bombay, Rangoon.
Ceylon.—Colombo.
Dutch East Indies.—Surabaya.
Siam.—Bangkok.

CHOLERA

India.—Bassein, Bombay, Calcutta, Madras, Moulmein, Rangoon.
Siam.—Bangkok.
French Indo-China.—Saigon.
China.—Canton, Shanghai.

SMALLPOX

India.—Bombay, Calcutta, Madras, Moulmein, Rangoon, Tuticorin, Vizagapatam.
French India.—Pondicherry.
Dutch East Indies.—Banjermasin, Pontianak.
China.—Canton, Shanghai, Hong Kong.
Japan.—Shimonoseki.
Kenya.—Mombasa.
Egypt.—Suez
Kwantung.—Dairen.
Manchuria.—Mukden.
Sarawak.—Kuching.

Returns for the week ended March 31 were not received from Balikpapan or Sabang, Dutch East Indies, or Basra, Iraq.

CANADA

Provinces—Communicable diseases—Week ended April 7, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from seven Provinces of Canada for the week ended April 7, 1928, as follows:

Disease	Nova Scotia	New Brunswick	Quebec [1]	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever				1				1
Influenza	6			3				9
Smallpox				9		12	13	34
Typhoid fever		2	12	9	1	1		25

[1] 1 case of poliomyelitis and 15 cases of typhoid fever reported from Province of Quebec for week ended Mar. 31, 1928.

Quebec Province—Communicable diseases—Week ended April 14, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended April 14, 1928, as follows:

Disease	Cases	Disease	Cases
Chicken pox	63	Scarlet fever	103
Diphtheria	43	Smallpox	20
German measles	15	Tuberculosis	59
Influenza	5	Typhoid fever	14
Measles	214	Whooping cough	6

Vital statistics—Quebec Province—February, 1928.—Births and deaths in the Province of Quebec for the month of January, 1928, were reported as follows:

Estimated population	2,650,000
Birth rate per 1,000 population	27.4
Death rate per 1,000 population	12.4
Infant mortality rate	126.3
Deaths from—	
Cancer	126
Cerebrospinal meningitis	2
Diphtheria	45
Diabetes	26
Diarrhoea	77
Heart disease	326
Influenza	108
Deaths from—Continued.	
Measles	15
Pneumonia	257
Poliomyelitis	2
Scarlet fever	12
Smallpox	0
Syphilis	4
Tuberculosis (pulmonary)	198
Tuberculosis (all other forms)	55
Typhoid fever	18
Violence	33
Whooping cough	32

The following table gives a comparison of the vital statistics of the Province of Quebec for the month of February of the years 1926, 1927, and 1928:

	February		
	1926	1927	1928
Birth	6,472	6,137	6,051
Marriages	971	1,145	1,025
Deaths	2,812	3,244	2,730
Deaths under 1 year	847	835	764

HAITI

Cape Haitien—Meningococcus meningitis—April 26, 1928.—Under date of April 26, 1928, an epidemic of meningococcus meningitis was reported in the region around Cape Haitien, Haiti.

IRAQ

Leprosy—1922-1927.—During the six years ended December 31, 1927, a total of 210 lepers was registered in the Iraq Health Directorate, of whom 199 were males, suggesting that a number of female lepers were not registered.

Of the registered cases approximately 56 per cent were anesthetic, 37 per cent nodular, and 7 per cent mixed. The places of origin, which are probably the places of infection, were as follows:

Places of origin	Males	Females	Total cases	Places of origin	Males	Females	Total cases
Baghdad Liwa	14	1	15	Kirkuk Liwa	3	0	3
Basra Liwa	20	0	20	Kut Liwa	11	0	11
Mosul Liwa	6	1	7	Muntafiq Liwa	17	1	18
Amarah Liwa	62	6	68	Sulaimani Liwa	2	0	2
Arbil Liwa				Tribal (unclassified)	6	0	6
Diwaniyah Liwa	10	0	10	Kurdistan	6	0	6
Diyalah Liwa	3	0	3	Persia	28	1	29
Dulaim Liwa	4	0	4	Afghanistan, etc	3	1	4
Hillah Liwa	3	0	3				
Kerbalah Liwa	1	0	1	Total	199	11	210

MEXICO

Puerto Mexico—Malaria—October-December, 1927—Campaign against hookworm infection, March, 1928.—Malaria was reported present with more than the usual rate of prevalence at Puerto Mexico, State of Vera Cruz, Mexico, during the period October-December, 1927. In March, 1928, a campaign against hookworm infection was instituted at Puerto Mexico and Minatitlan, with special reference to school children, the local units supplying the remedies necessary when gratuitous treatment was required.

SWITZERLAND

Basel—Vital statistics, 1926.—The population of Basel, Switzerland, in 1926, was estimated at 147,426. The birth rate for that year was 16.4 per 1,000 population; the death rate 11.7 per 1,000; and the infant mortality was 34.4 per 1,000 births. The following table gives the number of cases of the more common communicable diseases, and the deaths from these diseases for the year 1926:

Disease	Cases	Deaths	Disease	Cases	Deaths
Cerebrospinal meningitis	2		Smallpox	0	0
Chicken pox	364		Tuberculosis (pulmonary)		137
Diphtheria	84		Tuberculosis (miliary)		8
Measles	2,410	8	Tuberculosis (other forms)		35
Mumps	28		Typhoid fever	11	2
Puerperal fever	8	8	Whooping cough	259	2
Scarlet fever	139				

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

ASST. SURG. GEN. R. C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

MENINGOCOCCUS MENINGITIS IN THE UNITED STATES

An increase in the number of cases of meningococcus meningitis this year over the corresponding period of last year has been noted in the Public Health Reports (issues of April 6, 1928, p. 807, and April 27, 1928, p. 999).

During the eight weeks from March 4 to April 28, 1928, and the corresponding eight weeks of 1926 and 1927, forty-two States reported cases of meningococcus meningitis as follows:

	Cases
1926	438
1927	477
1928	1,036

These States had an estimated population of more than 104,000,000 in 1927.

The disease appears to be decreasing in the Mountain States, which have reported the highest case rates.

Reports of deaths for the year 1928 are available only from cities. The following table shows the numbers of cases of meningococcus meningitis and deaths from this disease reported by 7 large cities for the first 17 weeks of 1927 and 1928. The cities were selected for the reason that they reported a considerable number of cases.

Meningococcus meningitis cases and deaths reported by certain cities, January 1 to April 28, 1928, and corresponding period of 1927

	1927		1928			1927		1928	
	Cases	Deaths	Cases	Deaths		Cases	Deaths	Cases	Deaths
Chicago	50	23	133	66	New York City	77	46	284	148
Cleveland	8	3	29	9	St. Louis	14	4	44	16
Detroit	17	12	22	24					
Kansas City, Mo.	5	3	34	16	Total	242	125	587	304
Milwaukee	71	34	41	25					

It should be noted that, while the increase over preceding years is considerable, the number of cases is not large in proportion to the population.

THE INCIDENCE OF VARIOUS DISEASES ACCORDING TO AGE [1]

Hagerstown Morbidity Studies No. VIII [2]

By EDGAR SYDENSTRICKER, *Statistician, United States Public Health Service*

In this report it is proposed to place on record in some detail the results of the morbidity study in Hagerstown, Md , which bear upon the incidence of various diseases and conditions at different

The data are too voluminous to permit of a detailed discussion of each disease or a comparison with other morbidity records in a short paper. It is believed, however, that they will be of interest as they stand, not merely for the reason that they add to our morbidity experience, but also, and perhaps especially, because they are the results of the first study, of which we are aware, of the *incidence* of illness and disease during a period as long as 28 months in a general population group composed of persons as found in their homes—that is, of both sexes, all ages, engaged in the ordinary occupations of life, in a fairly typical inland small city in the eastern section of the United States

I. Scope and Method of the Study and Definition of Illness and Disease

The scope and method of the study have been discussed in detail in the first paper of this series and need not be repeated here except in so far as they may affect some particular phase of the results here presented. For proper interpretation of the data, however, it may be well to invite attention to certain definitions and procedures, as follows:

1. For every case of illness recorded, an attempt was made to obtain as complete a statement as possible of the specific disease or diseases responsible for it or of the condition which most accurately described it. Only 170, or less than one per cent, of the 17,847 illnesses had to be classified as "ill-defined and unknown." Of the total number (17,217) for which information as to medical and other service was avialable, 7,953, or 46 per cent, were attended by physicians, and in practically

all of these cases the diagnosis given by the informant at the home was reviewed by the attending physician shortly after the visit was made. If we omit "colds" and minor digestive disturbances, which numbered about 7,500, 65 per cent of the illnesses were attended and the diagnoses were reviewed by physicians. The facts that repeated visits were made to the same households and that 67 per cent of the total population enumerated were observed for at least 24 of the 28 months, are evidence, we believe, of a real attempt to ascertain not only the incidence, but also the cause of illness.[3]

2. In the interpretation of the data presented in this paper it is essential to keep in mind the following qualification: *The measure of the incidence of any specific disease was the extent to which it manifested itself in illness.* If it did not manifest itself in illness, it was not observed and, therefore, was not recorded. It follows, of course, that our results are not comparable with the results of intensive medical or physical examinations, and that defects and conditions indicative of ill health are not revealed unless they were major causes of illnesses recorded. Similarly, those morbid conditions which ordinarily are described as "below par," "not feeling very well," etc., or were of short duration and occasioned little discomfort, were not recorded. For example, many minor respiratory attacks were not reported. Less than 5 per cent of the illnesses for which exact durations were stated were one day or less in duration. Comparisons of our results with other morbidity records indicate that, in general, the illnesses we recorded were those which lasted over two days.

Thus the definition of "illness" employed in this study was not, as we have already pointed out, rigidly precise. The records obtained were of illnesses as reported by the household informant (usually the wife), either as experienced by herself or as she observed them in her family; thus the definition of the term can not be refined any further than the common understanding of the word. Furthermore, the records as obtained were of *attacks*, rather than illness in

[3] *Per cent of persons observed for specified number of months in the Hagerstown morbidity study*

Number of months under observation	Persons under observation specified number of months	
	Number	Per cent of total
28 months	3,202	37.3
26 months or more	5,140	49.8
24 months or more	5,787	67.4
18 months or more	6,824	79.5
14 months or more	7,528	87.7
12 months or more	7,794	90.8
9 months or more	8,085	94.2
6 months or more	8,340	97.1
4 months or more	8,431	98.2

the sense of ill health. As already emphasized, of those persons affected with some chronic condition, only those who suffered ill effects of this condition *during the period* came to notice. "Normal" reactions of the individual, considered by some as not symptoms of disease, although accompanied by some discomfort, may be said to be unrecorded. Although the reader is cautioned against putting too fine a point on this definition of illness, we believe that the illness recorded undoubtedly was a fairly accurate indication of disease incidence.

3. In only 660, or 3.7 per cent, of the total illnesses was more than one cause or condition recorded. One reason for the comparatively small number of cases with "contributory" and "joint" causes was the method used in classification. Sometimes the informant mentioned more than one condition in telling about an illness; but when these conditions were in the nature of symptoms which simply amplified the information as regards a single cause of illness, they were not tabulated as complications or contributory causes. For example, a person may have reported "indigestion" and a "headache" as the cause of illness, but only the "indigestion" was used to denote the condition. In other words, *symptoms* were not made contributory causes unless it seemed quite certain that they apparently represented a condition *separate* and *distinct* from the primary diagnosis. In such cases, symptomatic indications were tabulated as disease entities, even though they were sometimes complications of the primary disease. Thus, in the case of "colds" and "indigestion," the cold was made primary, but the indigestion was tabulated as a complication.

In the tables on the incidence of specific diseases which are presented in this paper, *both primary and contributory causes* are given as distinct diseases or conditions. Thus, in the foregoing instance, the "cold" is included under its appropriate title and "indigestion" under its appropriate title also.

The age groupings were chosen with the primary purpose of exhibiting the characteristic age curves of the various diseases. This was a rather difficult thing to do, and in some instances the groupings are probably not the best suited. It was thought best to retain one age classification throughout, however, except for a few diseases for which additional tables and graphs are given.

II. The Record of Diseases and Conditions

The basic data used in this report are given in Table A, entitled "Number of illnesses, by age groups, in which specified diseases or conditions were the sole or primary or contributory cause in a group of white persons in Hagerstown, Md., observed from December 1, 1921, to April 1, 1924."

The data are presented in considerable detail in order that they may be available to those who wish to use the statistics in various ways. For several diseases the numbers according to age groups are too small to yield dependable indications of age variations, but they are given for what they are worth in themselves, as well as to enable the student to make combinations to suit his particular purpose.

TABLE A.—*Number of illnesses, by age groups, in which specified diseases or conditions were the sole or primary or contributory cause in a group of white persons observed in Hagerstown, Md., December 1, 1921–March 31, 1924*

Disease or condition (numbers in parentheses refer to those given in the International List of Causes of Death, 1920)	Number of illnesses in which the specified disease or condition was a cause

III. Incidence Rates of Specific Diseases at Different Ages

In the following series of tables the age specific rates of the different diseases are given on an annual basis. The discussion is confined largely to brief explanatory comment and, in some instances, contains supplementary details; but we have relied upon the graphs to depict the principal results and indications that the data appear to yield. The number of cases and "years of life observed" upon which any rate is computed may be found by reference to Table A.

1. EPIDEMIC, ENDEMIC, AND INFECTIOUS DISEASES

(Int. List. Nos 1–42, except 11 and 31)

TABLE 1

Diseases and conditions	Annual rate per 1,000							
	All ages	0–4	5–9	10–14	15–24	25–44	45–64	65 and over
Total	88.7	353.4	293.7	50 8	15.8	11.4	10.1	9.9
Typhoid	1.2	.6	1 9	2.9	1.2	.6	.8	1.2
Measles	34.4	153.6	124.0	16.3	1.6	.4	------	------
Scarlet fever	2.1	5.1	7.6	4.1	.8	------	------	------
Whooping cough	22.6	117.6	67.5	7.0	1.2	.9	1.2	------
Diphtheria	2.7	6.2	8.6	4.1	.8	1.1	.8	------
Cholera nostras	2.2	.6	.5	2.8	2.0	2.4	4.3	3.7
Chicken pox	4.0	59.7	54.6	5.8	------	.2	------	------
German measles	1.1	1.7	5.7	1.2	------	.2	------	------
Tuberculosis, nonpulmonary	1.8	------	.5	.6	1.2	1.9	------	------

Of the total 1,465 cases included under the above heading, 1,174 were measles, whooping cough, and chicken pox, so that the age curve for the total for the group is influenced largely by these three diseases. The number of cases of the other diseases are too small to yield dependable indications according to age although some of the rates are interesting from the viewpoint of interepidemic incidence.

In view of the fact that measles, whooping cough, and chicken pox were quite prevalent during the period of study, their actual incidence (as contrasted with the incompletely reported incidence usually available [4]) according to age is not without significance. The accom-

[4] The annual rates based on our records and annual rates based on reports of physicians to the local health department are compared below.

Observed and reported incidence of measles, whooping cough, and chicken pox in Hagerstown Md. December 1, 1921–March 31, 1924

Disease	Annual incidence per 1,000 as—	
	Observed in home visits	Reported by physicians
Measles	34.4	9.0
Whooping cough	22.6	3.3
Chicken pox	14.0	2.2

See Hagerstown Morbidity Studies No. II.

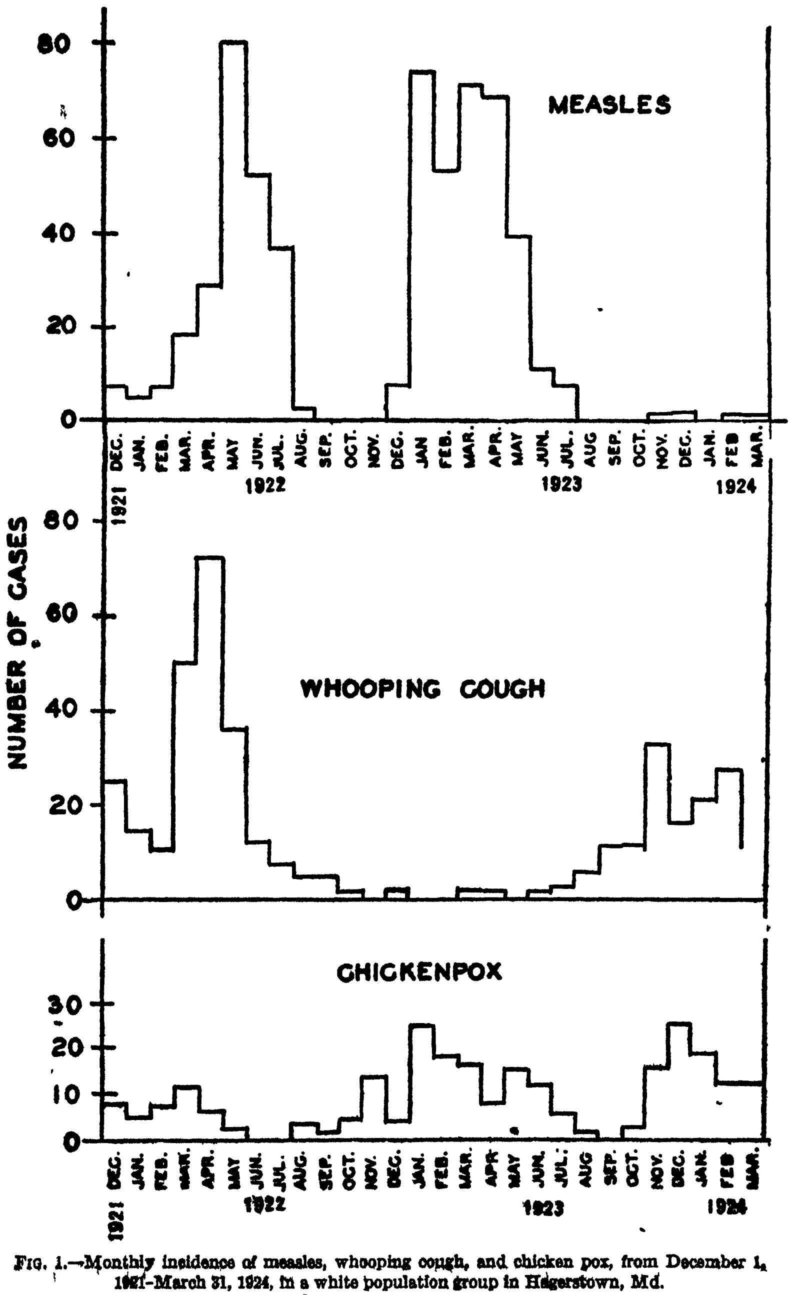

FIG. 1.—Monthly incidence of measles, whooping cough, and chicken pox, from December 1, 1921–March 31, 1924, in a white population group in Hagerstown, Md.

panying diagrams (fig. 1) exhibit the monthly numbers of cases and reveal a definitely epidemic prevalence of measles and whooping cough and perhaps of chicken pox.[5] For each of these diseases a more detailed tabulation according to age was made as follows:

TABLE 1a.—*Measles, whooping cough, and chicken pox*

Age	Annual rate per 1,000		
	Measles (568 cases)	Whooping cough (374 cases)	Chicken pox (232 cases)
Under 1 year	118	155	45
1 year	160	88	39
2 years	153	126	63
3 years	197	68	80
4 years	153	137	78
5 years	165	96	80
6 years	168	95	90
7 years	144	68	59
8 years	82	41	26
9 years	43	26	7
10 to 14 years	16	7	6
15 to 24 years	1.6	1.2	
25 to 44 years	.4	.9	.2
45 to 64 years		1.2	
65 years and over			

These rates have been plotted in Figure 2 and tell their own stories. The dotted lines were drawn by inspection and serve merely to suggest what the age curves might be if the irregularities due to small numbers were smoothed out.

2. "GENERAL" DISEASES

(Int. List Nos. 43-69)

TABLE 2

Diseases	Annual rate per 1,000							
	All ages	0-4	5-9	10-14	15-24	25-44	45-64	65 and over
Total	23.1	3.4	7.1	8.2	8.7	22.2	58.2	77.7
Cancer	1.3					1.3	3.9	6.2
Rheumatism	17.6	.6	5.2	6.4	6.7	16.2	44.3	67.9
Diabetes	1.0					.2	5.4	1.2
Others	3.2	2.8	1.9	1.8	2.0	4.5	4.7	2.5

The true prevalence of all diseases classifiable under this heading is not, of course, revealed by a record of the illnesses that they cause during a period of 28 months. The prevalence of acute rheumatism, which forms a large proportion of the total, is probably adequately

[5] The chronological variations in the incidence of illness from various causes will be presented in detail in a later paper.

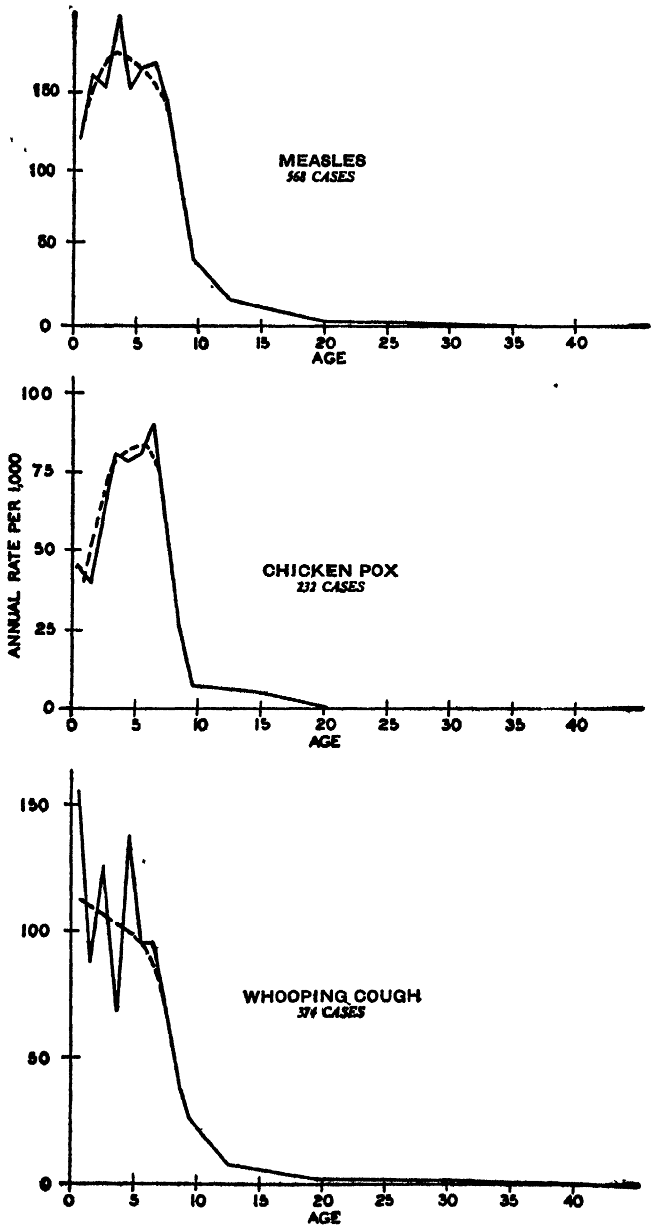

FIG. 2.—Incidence of measles, chicken pox, and whooping cough, among persons of different ages in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924. The dotted, smooth lines were drawn by inspection

recorded, but certainly this can not be said of diabetes or cancer. Our record of cancer and diabetes may be interpreted as indicating the prevalence of cases severe enough to require a physician's attendance, since every case recorded was attended by a physician. (See fig. 3.)

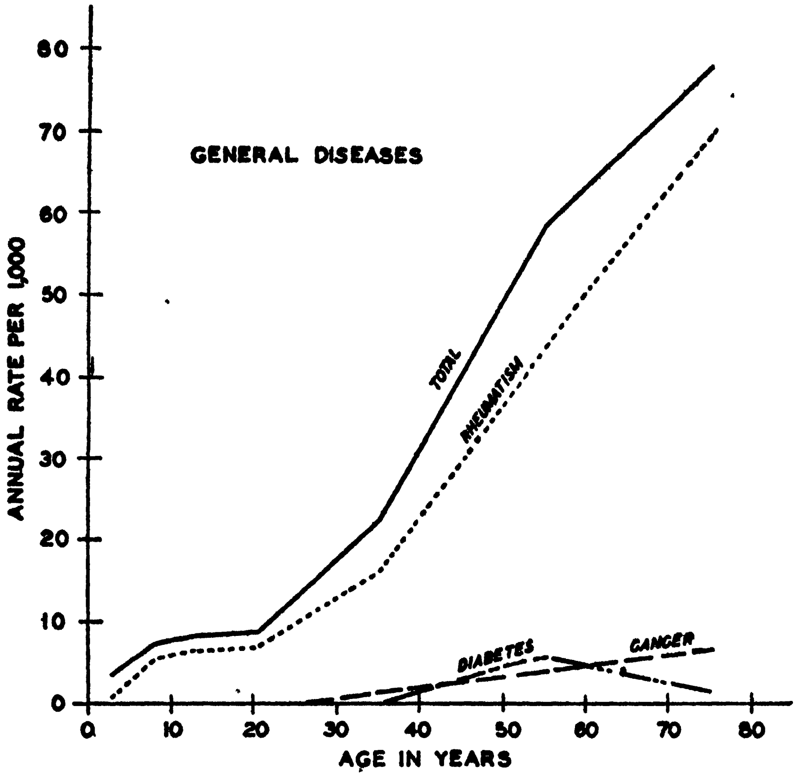

FIG 3 – Incidence of "general diseases" manifested in illness among persons of different ages in a white population group in Hagerstown, Md, December 1, 1921–March 31, 1924

3. DISEASES OF THE NERVOUS SYSTEM

(Int. List Nos 70–84, part of 205)

TABLE 3

Disease	Annual rate per 1,000							
	All ages	0–4	5–9	10–14	15–24	25–44	45–64	65 and over
Total	48.56	6.19	22.33	51.96	28.51	57.94	87.37	88.86
Apoplexy and cerebral hemorrhage	.91	.56				.43	1.16	9.87
Paralysis	1.63			.58		.22	3.11	19.75
Epilepsy	.67	.56		2.34	.79	.65	.39	
Chorea	1.21		1.43	8.17	.79		.39	
Neuralgia	7.83	.56	1.43	2.34	3.56	11.20	13.98	14.81
Neuritis and sciatica	5.75				1.19	8.40	15.92	11.11
Neurasthenia and nervous exhaustion	13.06	1.69	3.33	5.84	9.90	17.02	26.79	20.98
Headache	15.20	1.13	14.73	30.36	7.13	17.23	22.91	8.64
Other nervous conditions	2.78	1.69	1.43	2.34	5.15	2.80	2.72	3.70

The fact that "headache" is a symptom that characterizes no particular syndrome makes its inclusion under diseases of the nervous system rather doubtful. One has the choice of classifying illnesses described as "headaches" under "ill-defined and unknown" or of including them under some other group titles preferably (perhaps) the nervous system. We adopted the latter course after excluding, however, from the foregoing table all headaches that were reported as occurring in conjunction with a disease or condition of which headache may be a symptom. The rates given above are based on those indispositions and illnesses which were reported as "headache" without any other related condition, and the reader can reclassify them as he pleases. The other conditions specified in the table seem to be fairly definite from the diagnostic point of view, either because they are commonly recognized, as in the case of neuralgia or sciatica, or for the reason that the attending physician's diagnosis was recorded. The extent to which the specific conditions were attended by physicians is shown below:

TABLE 3a.—*Extent to which cases of nervous diseases and conditions resulting in illness were attended by physicians*

Disease or condition	Number of cases	Per cent attended by physicians
Apoplexy and cerebral hemorrhage	9	100
Paralysis	23	96
Epilepsy	9	56
Chorea	19	89
Neuralgia	100	38
Neuritis and sciatica	86	58
Neurasthenia and nervous exhaustion	164	80
Headache	237	11
Other nervous conditions	39	67

The age incidence of these conditions is shown graphically in Figure 4 and needs no further comment except on one or two details.

The high incidence of headache in the age group 10 to 14 is undoubtedly significant, although we are not able to say what specific condition it is directly associated with. It is corroborated by the more extensive records of absences due to "headaches" in the Hagerstown schools.[6]

[6] Collins (1) reported the following:

Sickness resulting in absence from school due to "headache and neuralgia" as reported by child or parent, in white schools, Hagerstown, Md., December, 1921–May, 1923

Age	Annual [a] rate per 1,000	Age	Annual [a] rate per 1,000
6	142	12	402
7	196	13	384
8	255	14	377
9	296	15	357
10	321	16–18	267
11	318		

[a] Per school year of 180 days

The rate quite definitely exhibited a maximum in the ages 10 to 14.

Whether or not all of the chorea was true chorea, it is impossible to say; all except two of the 19 cases were diagnosed by attending physicians, and all of the attacks were severe enough to result in illness. While 80 per cent of the cases recorded as "neurasthenia" and "nervous exhaustion" were so diagnosed by attending physicians, it is probable that this diagnosis was not infrequently used as a generic or vague term to designate a condition due to more specific causes. The higher incidence of paralysis than of apoplexy and cerebral

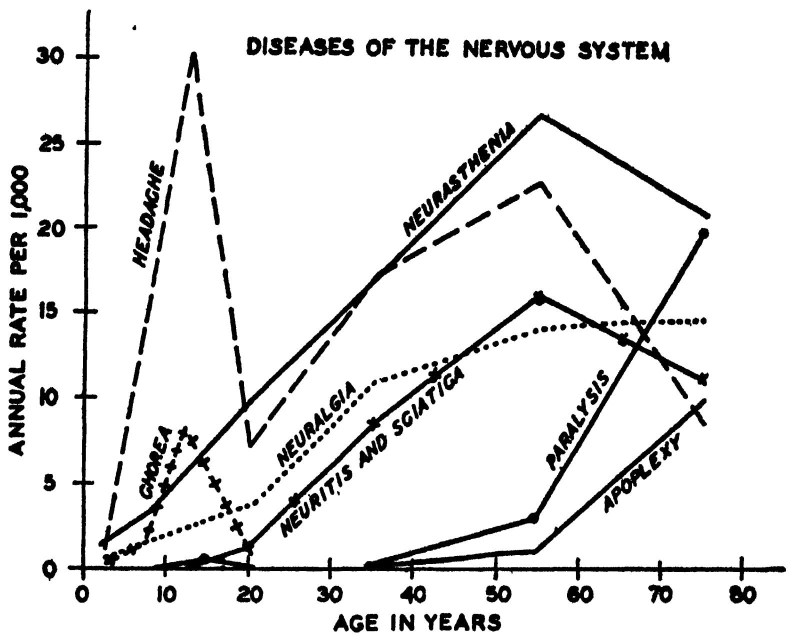

FIG. 4.—Incidence of certain diseases and conditions of the nervous system manifested in illness among persons of different ages in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

hemorrhage is due, of course, to the fact that the former included conditions continuing from lesions that occurred before our study was made, whereas the latter occurred during the 28 months of observation.

Lumbago and myalgia, in accordance with the International List of Causes of Death, are classified under "Diseases of the bones and organs of locomotion," but obviously belong with diseases of the nervous system. They are given immediately below.

4. DISEASES OF THE BONES AND ORGANS OF LOCOMOTION

(Int. List Nos 155-158; part of 205)

TABLE 4

Disease	Annual rate per 1,000							
	All ages	0-4	5-9	10-14	15-24	25-44	45-64	65 and over
Total	7.02	1.13	2.38	2.92	1.98	10.55	13.59	16.04
Lumbago, myalgia, myositis	3.15	.56	1.43	1.17	------	4.74	7.38	6.17
Backache (part of 205)	2.30	------	------	.58	.79	4.09	3.49	6.17

"Backache" may be regarded as a symptom of any of several causes or as an indeterminate name for lumbago. The "diseases of the bones" were too few to classify separately.

5. DISEASES AND CONDITIONS OF THE EYE AND ANNEXA

(Int List No 85)

TABLE 5

Disease	Annual rate per 1,000							
	All ages	0-4	5-9	10-14	15-24	25-44	45-64	65 and over
Total	8.42	8.44	16.16	16.93	4.46	5.38	6.60	7.40
Conjunctivitis, bacillary (pink eye)	2.00	2.25	4.28	5.25	.79	1.08	1.16	------
Conjunctivitis, other and "sore eye"	3.57	3.94	8.08	6.42	1.52	1.94	3.88	1.23
Sty	1.09	1.69	1.90	1.75	.79	1.29	------	------
Other "eye trouble"	1.70	.56	1.90	3.50	1.19	1.08	1.55	6.17

In the absence of adequate eye examinations, it is impossible of course to interpret the rates given above except in a very general way. Most of the conditions classified under "other eye trouble" were attended by physicians and were eye defects rather than acute attacks of disease. We may, therefore, roughly divide the incidence of the eye conditions recorded into two categories: (*a*) Those of an acute nature due principally to infections, such as sties, pink eye, and other forms of conjunctivitis, and (*b*) those due to defects. The rates for these two groups have been plotted in Fig. 5, as well as the curve for markedly defective vision (20/50 or worse in one or both eyes) which has been published for a large group by Collins and Britten (2). A comparison of the curve for defective vision with that for "other eye trouble" suggests that the conditions classified under the latter were due principally to defects. Although some of them occurred among children of school age, the "other eye troubles" increased with age; the incidence of acute disabilities, due princi-

pally to infections, on the other hand, occurred chiefly among children. The incidence of specific conditions in the latter group is shown graphically in Figure 6.

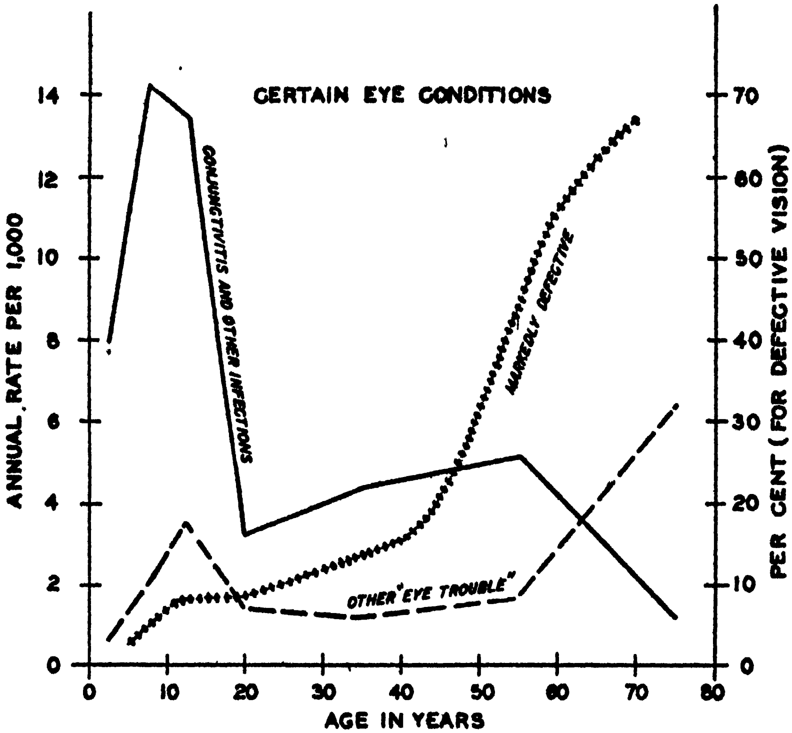

FIG. 5 —Incidence of certain eye conditions among persons of different ages in a white population group in Hagerstown, Md., and of markedly defective (20/50 or worse) vision according to Britten and Collins

6. DISEASES OF THE EAR AND MASTOID PROCESS

(Int. List No. 86)

TABLE 6

Disease	Annual rate per 1,000							
	All ages	0-4	5-9	10-14	15-24	25-44	45-64	65 and over
Total	15.01	40.52	37.06	26.27	7.92	5.17	2.33	2.47
Otitis media	10.05	35.46	20.91	15.76	2.77	4.31	1.55	1.23
Mastoiditis	.67		1.43		2.38	.43		
Earache	3.21	3.94	12.35	8.17	1.58			1.23

The fact that diseases of the ear so far as they are manifested in illness are largely confined to children is clearly apparent.

The record of absences in the Hagerstown schools due to "earache and ear diseases" (*1*) exhibits the same curve in greater detail for children of school age.

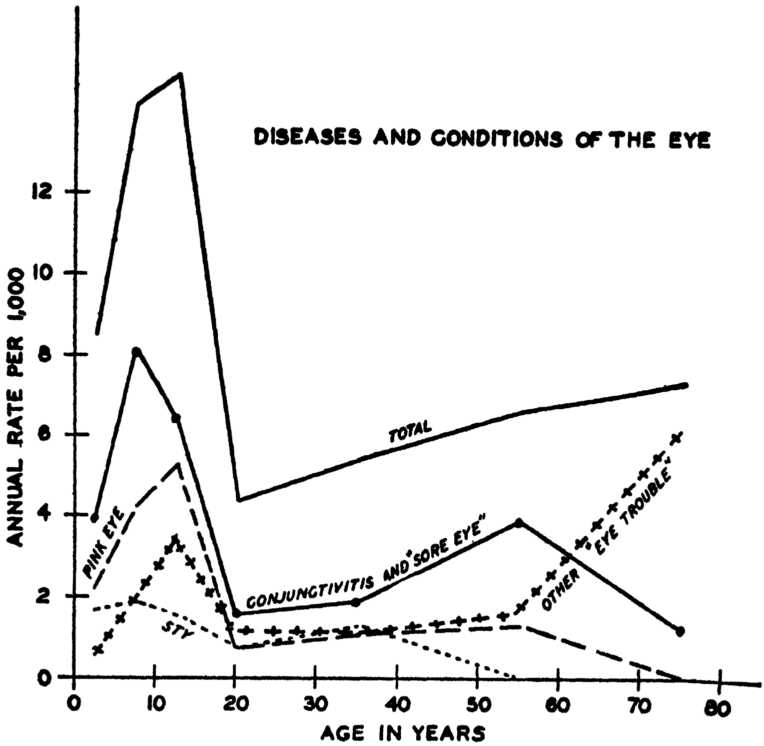

FIG 6.—Incidence of certain diseases and conditions of the eye manifested in illness among persons of different ages in a white population group in Hagerstown, Md, December 1, 1921–March 31, 1924

TABLE 6a.—*Absences due to "earache and ear diseases" in Hagerstown schools December, 1921–May, 1925*

Age	Earache and ear diseases		Earache		Ear diseases	
	Number of cases	Rate per 1,000 *	Number of cases	Rate per 1,000 *	Number of cases	Rate per 1,000 *
6	88	102	71	82	17	19.8
7	131	76	116	67	15	8.7
8	128	73	112	64	16	9.1
9	107	66	93	57	14	8.7
10	69	43	54	33	15	9.3
11	69	46	52	35	17	11.4
12	63	49	54	42	9	7.0
13	40	34	32	27	8	6.8
14	33	33	24	24	9	9.1
15	16	23	11	16	5	7.3
16-18	13	13	6	6	7	7.1

* Rate per 1,000 children per school year of 180 school days.

Otitis media was shown quite definitely to be a disease of children, and followed closely the curve of infectious diseases (fig. 7). The number of cases of mastoiditis is too small to offer any evidence as to variations in incidence according to age. "Earache" must be regarded as a symptomatic term under the general title of ear diseases and conditions. Its relatively infrequent occurrence among children under 5 years of age as compared with its higher incidence in the age

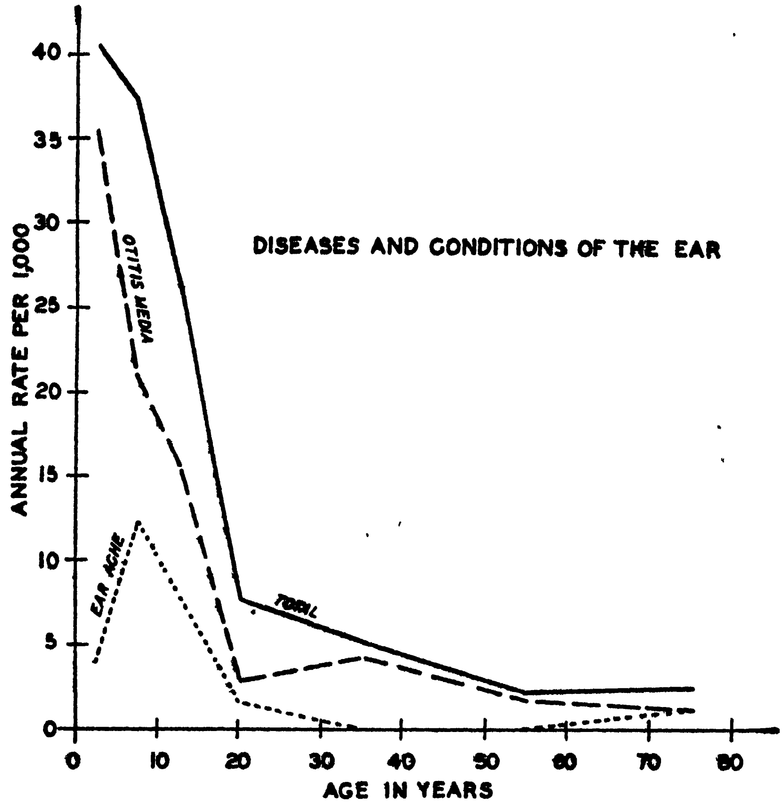

FIG. 7.—Incidence of certain diseases and conditions of the ear manifested in illness among persons of different ages in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

period 5 to 9 years is probably more apparent than real; it is doubtless due in part to the fact that it is a subjective rather than an objective symptom and in part probably to a tendency to call in a physician in cases of earache more frequently for younger children than for older. This possibly increases the recorded incidence of otitis media among young children.

7. DISEASES OF THE CIRCULATORY SYSTEM

(Int. List Nos. 87-96)

TABLE 7

Diseases and conditions	Annual rate per 1,000							
	All ages	0-4	5-9	10-14	15-24	25-44	45-64	65 and over
Total	24.04	12.38	10.93	18 10	11.09	15.72	43.88	117.24
Diseases of the heart	13.44		2.38	9 92	7.13	9.69	25.24	74.05
Arteriosclerosis	1 94						1.55	34.56
High blood pressure	1.82				.40	.86	8 15	4.94
Hemorrhoids	1.09				40	1 94	3.11	
Adenitis	3.45	11.82	6.18	6.42	2 38	.86	.78	
Nosebleed and other hemorrhage	1.03	.56	1.90	.58	.40		2.72	3.70
Other circulatory	1.27		.48	1.17	.40	2.37	2 33	

The caution already emphasized, that our data are not records of defects as discovered by medical examination and clinical observation but records of illness due to more or less specific conditions, is particularly pertinent in interpreting the age incidence of illnesses

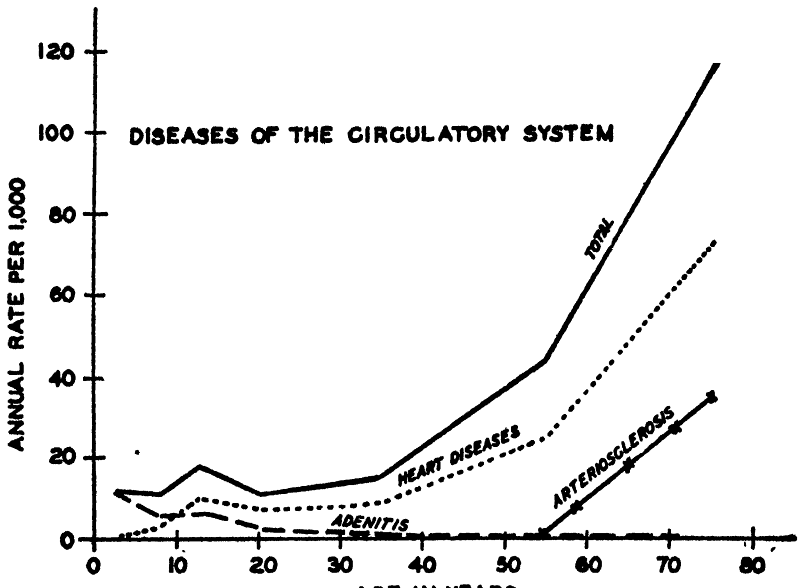

FIG. 8.—Incidence of diseases of the circulatory system manifested in illness among persons of different ages in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

due to circulatory diseases. Yet, for the most part, these illnesses were real disabilities, and 83 per cent of the 287 cases were attended by physicians.

The incidence of illness due to circulatory diseases and conditions among children and adolescents was due in part to glandular inflammation, especially in the ages under 10 years. (Fig. 8.) Diseases of the heart were relatively more frequent causes of illness in the age period 10–14 than at younger ages or until adult life, an indication

which is reflected in the age specific mortality rate for this group of causes. This indication appeared also in the records of absences due to heart conditions among the Hagerstown school children during (1) the period 1921–1925. Although the number of cases (60) is small, a variation according to age seems to be manifested within the school-age period, as follows:

TABLE 7a.—*Absences due to heart conditions in the Hagerstown schools, December, 1921, to May, 1925*

Age	Rate per 1,000 [a]	Number of cases	Age	Rate per 1,000 [a]	Number of cases
6	3.5	3	12	7.7	10
7	1.2	2	13	5.1	6
8	2.8	5	14	7.0	7
9	1.9	3	15	2.9	2
10	5.6	9	16–18	3.0	3
11	6.7	10			

[a] Rate per 1,000 children per school year of 180 school days.

The familiar rise in prevalence of heart disease in middle and old age is evidenced in these morbidity records as well as in mortality experience, but the rise of mortality from heart disease as age advances is at a much more rapid rate than that of the morbidity rate. If we compare the curve shown in Figure 8 with the mortality curve, for example, in the original registration States for 1920, the ratio of illnesses to deaths is about 30 at 15–24 years, 20 at 25–44, 8 at 45–64, and only 2 after 64 years.

8. RESPIRATORY DISEASES

(Int. List Nos. 11, 31, 97–107, 109)

TABLE 8

Disease or condition	Annual rate per 1,000: All ages	Under 5	5–9	10–14	15–24	25–44	45–64	65 and over

Other operations of nasal fossae	.5	------	------	------	1.6	.4	.4	------

[a] Based on records from February 1, 1923–March 31, 1924.

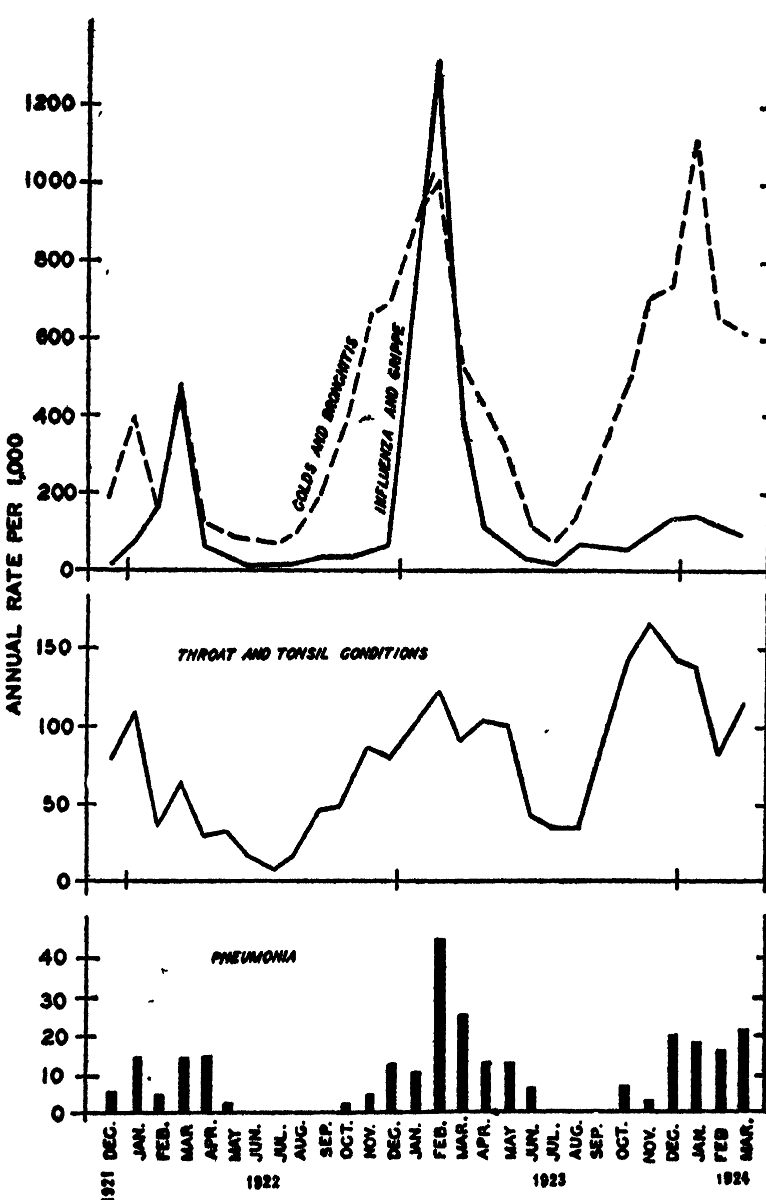

FIG. 9.—Monthly incidence of certain respiratory diseases and conditions in a white population group in Hagerstown, Md., December 1, 1921-March 31, 1924

Many minor respiratory affections were not included in the records we obtained. This was evident at the time the study was made, and is also shown to be true by later studies of the United States Public Health Service, which, by obtaining reports at much shorter intervals, showed the respiratory rate to be much higher than that recorded for the Hagerstown group.[7] Again, attention may be invited to the fact that nearly all the cases recorded in the Hagerstown study were illnesses in the common understanding of the term and, therefore, excluded respiratory attacks which, however definite they may have been clinically, were not accompanied by that degree of malaise which ordinarily is denoted as illness.

Since only 34 per cent of the respiratory cases recorded were attended by physicians, it was difficult to designate many of them by a more specific diagnostic term than that which the lay informant would ordinarily use. During the first half of the study we obtained information that was specific enough to make a rough classification into (1) influenza and grippe, (2) pneumonia, (3) pleurisy, (4) tonsillitis, (5) sore throat, (6) quinsy, (7) other diseases of the pharynx, (8) hay fever, (9) asthma, and (10) pulmonary tuberculosis. The remainder were grouped under a general heading (11) "Other diseases of the respiratory system" which included bronchitis, "bronchial colds and coughs," "chest colds," etc. In the second half of the study an attempt was made to obtain more specific information with the result that we were able to refine our classification and add the following: (12) Coryza and rhinitis, (13) bronchitis, and (14) "chest colds," "cough," and "bronchial conditions." This refinement probably had the additional effect of increasing the number of specific tonsil and throat conditions in the second 14 months of our study over what would have been recorded had no change in method of inquiry been made.

As the classification finally stands, however, we feel that the differentiations are roughly accurate from the point of view of present clinical knowledge. Obviously the distinction between "colds" and "influenza and grippe" is not clear, as the accompanying graphs of their monthly incidence suggest (fig. 9), since peaks in "colds" occur simultaneously with peaks in influenza. The age curves for the two conditions (fig. 10) are also quite similar, except for children under 5 years of age—an exception that can be accounted for by the inability of small children to tell the subjective symptoms ordinarily associated with influenza or grippe. But the other classes or kinds of

[7] A study based on semimonthly reports from a group of medical officers of the Army, Navy, and Public Health Service and members of several college faculties upon the incidence of respiratory attacks among themselves and members of their families showed a rate of 2.009 per 1,000 during 1924 (3). A similar study for several thousand college students reporting upon themselves showed a rate of 2,877 per 1,000 during the period June 1, 1924–May 30, 1925.

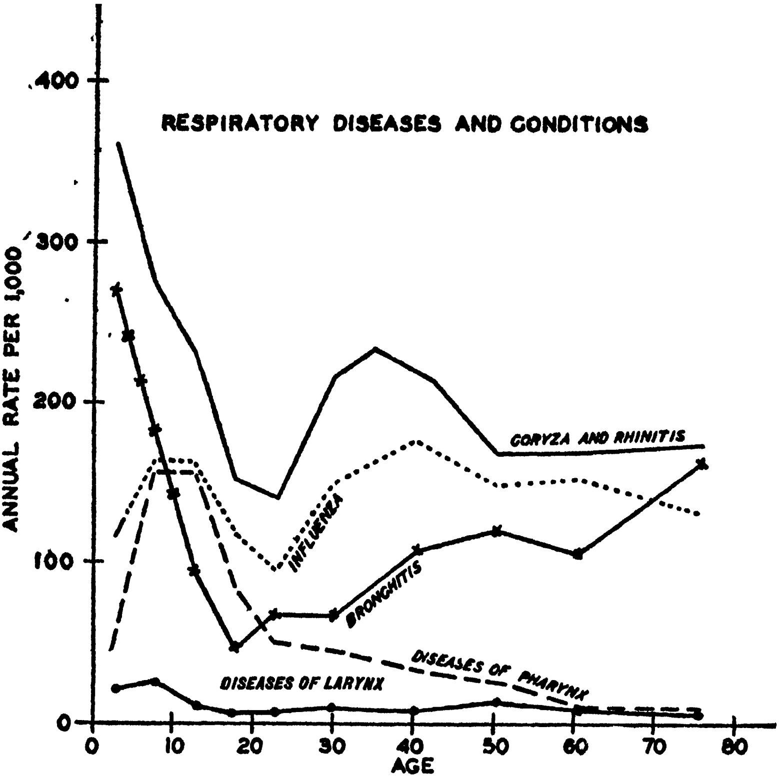

FIG 10.—Incidence of respiratory diseases and conditions manifested in illness among persons of different ages in a white population group in Hagerstown, Md, December 1, 1921–March 31, 1924

respiratory affections and diseases seem to be fairly well differentiated. In the first place, a considerable proportion of each were diagnosed by attending physicians, as the following table shows:

TABLE 8a.—*Proportion of cases of various respiratory diseases that were attended by physicians*

Disease or condition	Number of cases	Per cent attended by physicians
Pulmonary tuberculosis	48	98
Pneumonia	111	97
Pleurisy	33	88
Tonsillitis	465	73
Influenza and grippe	2,317	67
Other diseases of the pharynx	99	65
Hay fever and asthma	86	47
Laryngitis	92	36
Croup	86	33
Sore throat	497	21
Colds, unqualified	828	14
Coryza	1,780	7

In the second place, the age curves suggest fairly definite differences. Referring first to Figure 10, bronchitis is in clear distinction to coryza and to influenza on the one hand, and to diseases of the pharynx and larynx on the other hand. Considering tonsil and throat conditions (fig. 11), the age curves for pharyngeal conditions is quite different from those for laryngitis and also for croup.[8]

The number of cases of asthma, hay fever, pleurisy, and tuberculosis is perhaps too small to be of general interest, but the rates

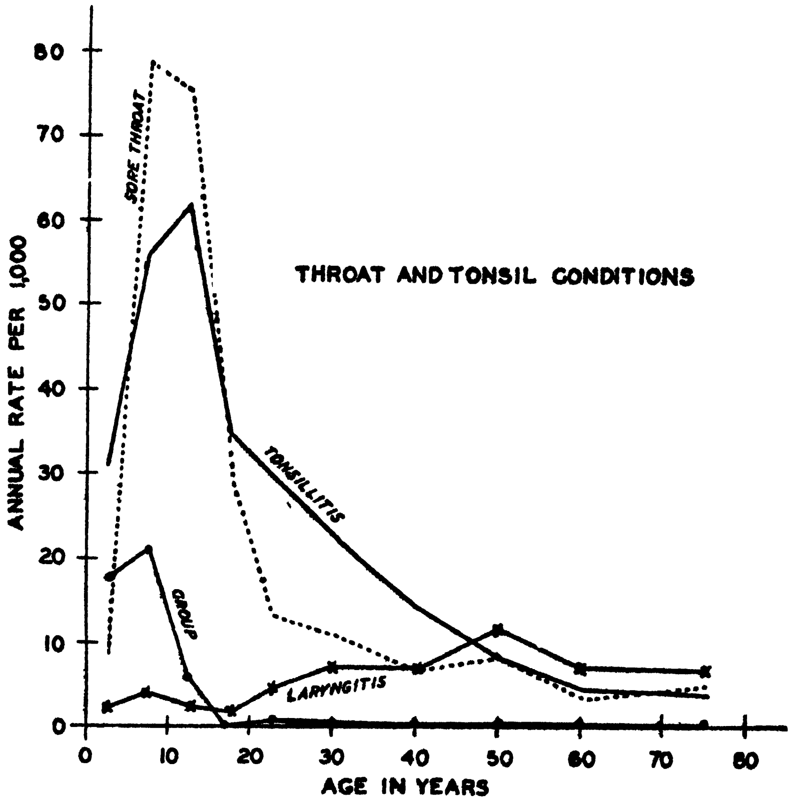

FIG 11 —Incidence of throat and tonsil conditions manifested in illness among persons of different ages in a white population group in Hagerstown, Md*, December 1, 1921-March 31, 1924

are plotted in Figure 12 as a record of our experience. In general, they conform to the indications afforded by such other morbidity data as are available. With respect to tuberculosis, it may be pointed out that only active cases resulting in some degree of disability during the period of observation were recorded.

[8] The epidemiological and etiological evidence bearing on this point is presented and discussed in detail by Collins (4) in his monograph "An Epidemiological and Statistical Study of Tonsillitis, Including Related Throat Conditions." The Hagerstown data will be considered in greater detail in a review of the morbidity records from all sources bearing on respiratory attacks, which is in preparation.

9. DISEASES OF TEETH AND GUMS

(Int. List No., Part of 108)

TABLE 9

Disease or condition	Annual rate per 1,000							
	All ages	0-4	5-9	10-14	15-24	25-44	45-64	65 and over
Total	8.23	1.13	9.98	18.68	8.31	9.05	6.21	2.47
Abscesses	3.21	0.56	1.90	6.42	4.75	3 66	3.11	------
Toothache	2.91	0.56	5.70	10.51	2.38	2.37	------	------

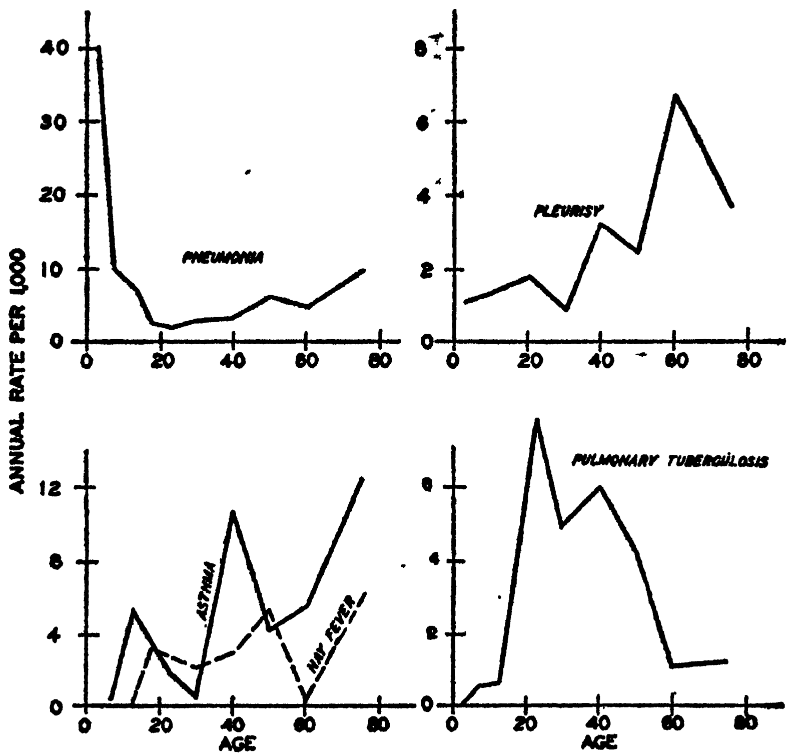

FIG. 12.—Incidence of certain respiratory diseases and conditions manifested in illness among persons of different ages in a white population group in Hagerstown, Md., December 1, 1921-March 31, 1924

This record can not, of course, be interpreted as indicating the prevalence of defective teeth and diseased gums. It indicates nothing more than the incidence of diseases and conditions that manifested themselves in abscesses and in pain severe enough to result in temporary disablement. About 60 per cent of these cases caused the patient to go to a dentist or a physician.

In so far as this record is suggestive, it indicates a relatively high incidence of dental and gum conditions in the age periods 10–14 and 15–24 after the permanent teeth have developed. This indication is also given by the larger number of records for the school ages collected by Collins (*1*) from the Hagerstown schools.

10. DISEASES AND DISORDERS OF THE DIGESTIVE SYSTEM

(Int. List Nos. 110–127; part of 108 and of 205)

TABLE 10

Disease	Annual rate per 1,000							
	All ages	0–4	5–9	10–14	15–24	25–44	45–64	65 and over
Total	102.01	158.71	148.25	130.18	61.76	71.29	109.11	101.20
Ulcers of stomach and duodenum	.73	------	------	------	.40	1.08	2.33	------
Indigestion and upset stomach and nervous indigestion	44.74	69.23	77.93	58.96	24.55	28.65	44.26	48.13
Stomach trouble and nausea	8.29	7.32	19.01	14.01	2.77	5.38	7.38	9.87
Diarrhea	13.26	58.53	7.60	9.92	6.33	8.18	8.15	7.40
Intestinal parasites	1.30	7.32	3.33	1.17	------	.22	------	------
Appendicitis	5.99	.56	4.28	7.50	12.27	5.38	6.21	------
Hernia	1.63	.56	.48	.58	.40	1.72	4.66	3.70
Constipation	.85	1.13	------	------	------	1.29	1.16	3.70
Other intestinal, including obstructions	1.51	1.13	.95	2.92	.79	.86	3.49	1.23
Biliary calculi	4.36	------	------	.55	2.38	7.97	7.77	2.47
Cholecystitis	1.94	------	.48	.58	------	1.72	6.21	3.70
Jaundice	2.72	3.94	9.98	3.50	1.98	.65	1.16	------
Other liver	1.88	.56	.95	1.17	.40	.65	6.21	7.40
"Biliousness"	10.41	4.50	20.91	27.44	8.71	4.31	8.54	11.11

Since only 58 per cent of illnesses reported as due to digestive disorders and diseases were attended by physicians, anything approaching diagnostic exactness for every case was impossible in this group. In the foregoing table, the classification has followed rather closely the terminology of the information as given, excepting cases under the following titles, nearly all of which were attended by physicians: Ulcers of stomach and duodenum, diarrhea (under 2 years of age), appendicitis, hernia, biliary calculi, cholecystitis, and jaundice. For the other cases, perhaps a very broad classification may be attempted, as follows: (*a*) Indigestion, upset stomach, nervous indigestion, stomach trouble, nausea (when not a symptom of some disorder specifically stated) which we may designate as "indigestion and upset stomach"; (*b*) "biliousness," with which may be placed "other liver conditions"; and (*c*) diarrhea. The classification is made partly on grounds that are apparent and partly by reason of similarity and dissimilarity of age curves, so that, as shown in Figure 13, diarrhea exhibits a definitely high incidence among children under 5 years of age, and thereafter does not vary greatly according to age; "indigestion and upset stomach"—some of which may have been attended by diarrhea, it is true—had a high incidence among children under 15, with its peak between 5 and 10

years; "biliousness" was less commonly reported, but was relatively frequent in the age period 5 to 9 years and was most frequent in the 10 to 14 years period. The incidence of illnesses classified under the last two headings was lowest in the young adult period, but rose gradually as age advanced.

The age curves of jaundice, appendicitis, biliary calculi, cholecystitis, and hernia have been plotted in Figure 14 and are in general accord with textbook observations. It is believed that they are

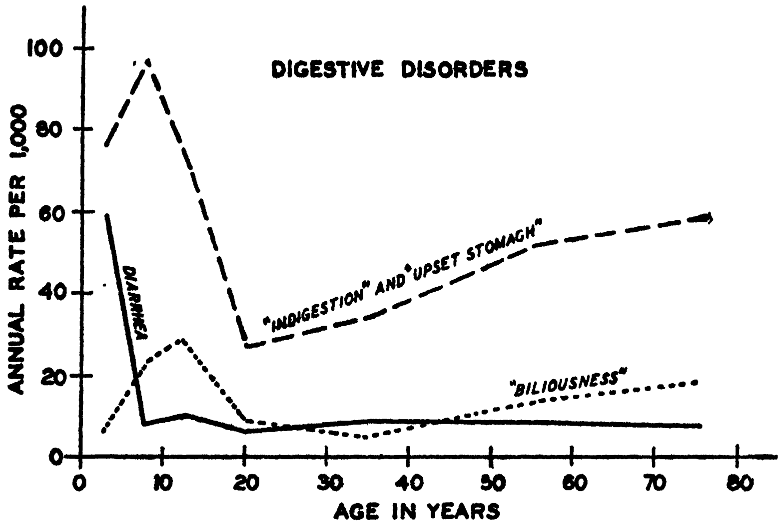

FIG. 13.—Incidence of digestive disorders manifested in illness among persons of different ages in a white population group in Hagerstown, Md., December 1, 1921-March 31, 1924

especially interesting for the reason that, so far as we are aware, they are based on a record of recognized cases (i. e., resulting in illness and attended by physicians) in a definitely enumerated general population group.

11. DISEASES OF THE KIDNEY AND ANNEXA

(Int. List Nos. 128-134)

TABLE 11

Disease or condition	Annual rate per 1,000: All ages	0-4	5-9	10-14	15-24	25-44	45-64	65 and over
Total	14.35	9.00	5.70	6.42	4.36	10.77	30.29	66.64
Nephritis	5.03	.56	.48	1.75	2.38	1.72	12.43	38.26
"Kidney trouble," unqualified	5.51	7.88	3.33	4.67	1.98	5.82	7.38	12.34
Calculi of urinary passages	.85					.65	3.11	3.70
Cystitis	1.39					.86	3.88	8.64
Other "bladder trouble"	1.45	.56	1.90			1.29	3.49	3.70

The rates in the table above, it may be emphasized, can not be interpreted as revealing the true prevalence of the diseases and conditions specified; they merely show the frequency of illnesses in which these diseases and conditions were stated to be causes during the period of the study. Of the 175 cases in which they were so recorded, 86 per cent were attended by physicians, and on approximately that proportion the attending physicians recorded the diagnoses as reported. The remaining 14 per cent consisted chiefly of cases reported as "kidney trouble."

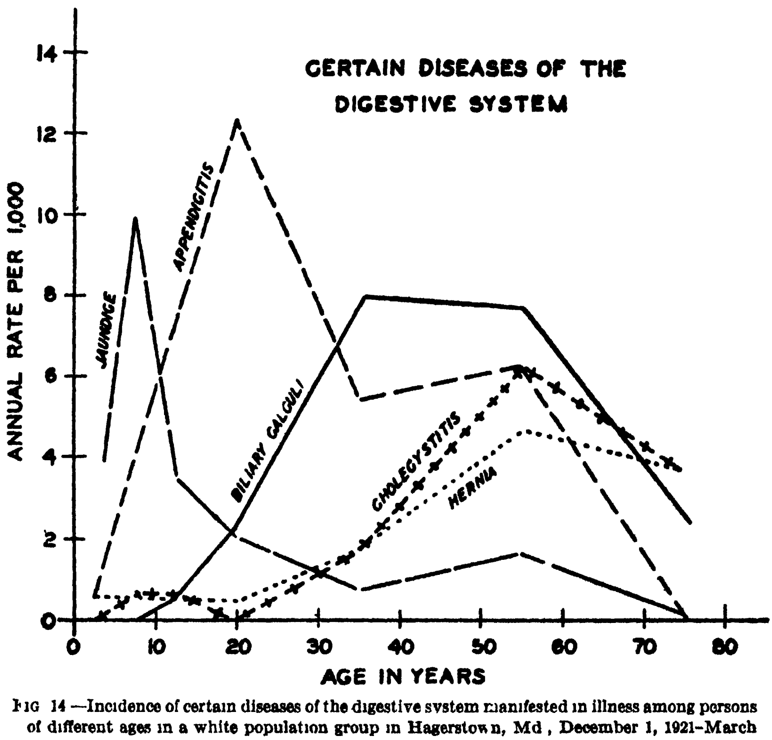

FIG 14 —Incidence of certain diseases of the digestive system manifested in illness among persons of different ages in a white population group in Hagerstown, Md , December 1, 1921–March 31, 1924

Except for some prevalence of a condition or conditions vaguely reported and diagnosed as "kidney trouble" in children and in the younger adult ages, it is quite evident that diseases and conditions in this group caused illness in middle and old age, especially in old age, to a greater extent than at younger ages.

The age curve of illness from nephritis is generally similar to that for mortality from acute nephritis and Bright's disease, but the ratio of cases to deaths decreases rapidly with age. Even if we include all illnesses from kidney conditions, such a ratio of cases to deaths would show a marked decline. Using the 1920 mortality rates for

the registration area, the ratio of the Hagerstown illnesses rate (assuming it to be representative in some degree) to the death rate declined from about 70 under 15, to 40 at 15–25, 20 at 25–44, 10 at 45–64, and 5 at 65 and over. The morbidity rates and these ratios mean nothing more, of course, than that as age advances, not only does the incidence of the disease increase but its fatality does also. Our record of cases and deaths in the population observed is too scanty and too brief to permit of any attempt to ascertain or estimate fatality rates.

12. NONVENEREAL DISEASES OF THE GENITO-URINARY SYSTEM

(Int. List Nos. 135–142)

TABLE 12

Disease or condition	Annual rate per 1,000							
	All ages	0–4	5–9	10–14	15–24	25–44	45–64	65 and over
Total [a]	13.02	1.13	1.43	8.17	17.02	21.11	17.47	7.40
Diseases of male organs [b]	1.50	2.12	1.83	1.18	.83	.46	.80	11.56
Salpingitis [c]	2.47	------	.99	------	4.53	4.84	1.51	------
Tumor and cysts of ovary and uterus [c]	2.11	------	------	------	2.26	4.44	1.51	2.15
"Menstrual trouble" [c]	6.11	------	------	13.84	15.85	5.26	4.52	------
Menopause [c]	4.81	------	------	------	------	6.05	18.09	------
Others of female genital organs [c]	8.34	------	------	1.15	9.06	18.56	7.54	2.15

[a] Rates computed on males and females. [b] Rates computed on males. [c] Rates computed on females.

The rates given above are probably based on too few cases to be in any degree typical, but they are not without interest. With the exception of 22 of the 47 cases of "menstrual troubles," practically all of the cases in this group were attended by physicians. The data represent, therefore, the prevalence of these conditions in our population to the extent that they come to the attention of physicians by reason of illness.

13. THE PUERPERAL STATE

(Int. List Nos. 143–150)

TABLE 13

Condition	Annual rate per 1,000 females			
	10–14	15–24	25–44	45–64
Total	2.31	84.55	110.98	2.26
Abortion and stillbirth	1.15	3.02	11.80	------
Confinements	------	74.73	87.17	------
Other puerperal conditions	1.15	6.79	12.51	2.26

The annual birth rate for our population was 19.6. Based on females aged 15–44, the birth rate was 65.2. The stillbirth (and abortion) ratio was 10.2 per 100 live births—an extremely high ratio when compared with records ordinarily published in vital statistics.[9] Obviously this can not be taken to indicate the occurrence of an unusual frequency of stillbirths as there was every reason to believe that the ratio for the population studied would not be higher than the average. Rather, the reason lies in the fact that we were able to secure a record of a larger proportion of stillbirths than is ordinarily reported and, in addition, a partial record of abortions. Our record is, we believe, probably not far wrong, since the field assistants made repeated visits to the same households.

14. DISEASES OF THE SKIN AND CELLULAR TISSUE

(Int List Nos. 151-154; part of 205)

TABLE 14

Disease	Annual rate per 1,000							
	All ages	0–4	5–9	10–14	15–24	25–44	45–64	65 and over
Total	19.43	39.96	40.39	33.27	10.69	10.34	7.38	14.81
Furuncle	4.66	3.38	9.03	6.42	4.75	4.31	2.33	2.47
Abscess	1.88	1.69	1.90	1.75	1.58	2.80	.78	1.23
Scabies and itch	1.45	3.38	3.80	5.84	------	------	------	------
Impetigo contagiosa	1.51	3.94	4.28	2.34	1.19	.43	------	------
"Sores" on body	4.06	15.20	10.93	8.17	.40	.43	------	------
Hives and rash	2.91	7.88	6.18	3.50	1.98	.86	1.94	1.23
Other and unqualified skin	2.97	4.50	4.28	5.25	.79	1.51	2.33	9.87

It was difficult to classify the various skin affections that were recorded except in those instances in which a physician's diagnosis was obtained. Hence the incidence of specific diseases included in the above table has probably been understated, although their variations according to age are roughly indicated. The percentages of the cases, as classified above, which were attended by physicians were as follows: Furuncle, 48 per cent; abscess, 82; impetigo, 71; scabies and itch, 52; rash, 39; hives, 47; "sores" on body, 28; other, 89; total 55. The incidence of rash, impetigo contagiosa, and "sores" was greatest among children under 10 years of age; of scabies in the age period 10–14; of furuncles and abscesses under 45 years of age, with its peak in the 5–9 age period. Some of the more specific diseases have been plotted on Figure 15.

[9] The stillbirth ratio for whites in the birth registration area was 3.8 per 100 live births in 1925 and for whites in Maryland was 5.8.

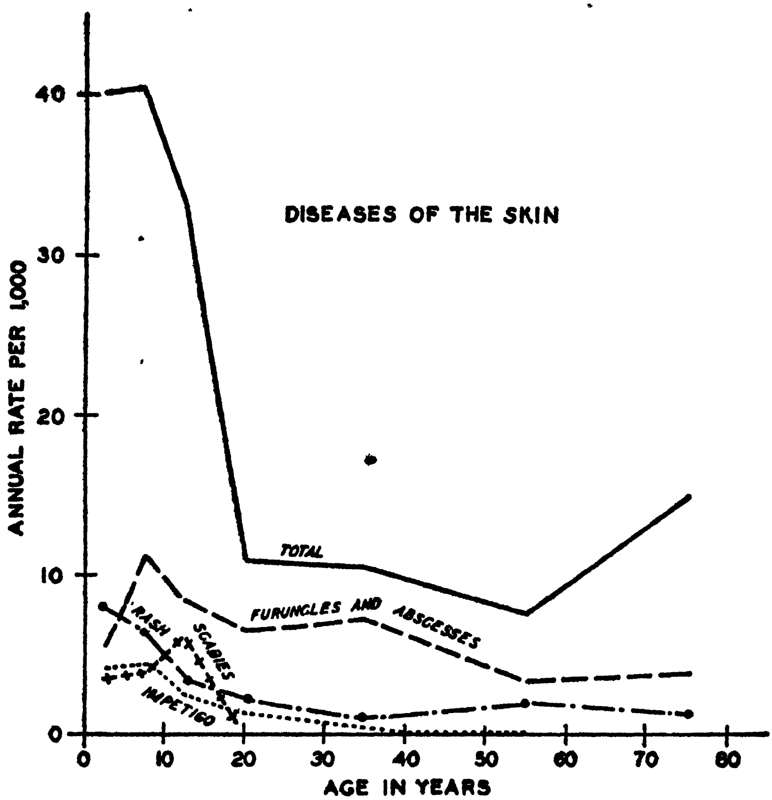

FIG. 15.—Incidence of diseases of the skin and cellular tissue manifested in illness among persons of different ages in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

15. CONGENITAL MALFORMATIONS AND EARLY INFANCY, SENILITY, AND ILL-DEFINED AND UNKNOWN CAUSES

(Int. List Nos. 159–163, 164, 205)

TABLE 15

Cause	Annual rate per 1,000							
	All ages	0–4	5–9	10–14	15–24	25–44	45–64	65 and over
Congenital malformations and "early infancy"	1.15	7.32	0.95	1.75				
Senility	.85							17.28
Ill-defined and unknown	10.29	26.45	8.55	9.34	4.36	7.73	10.48	13.68

The foregoing table requires little comment. The largest proportions of ill-defined or unknown causes of illness were, as might be expected, for young children and old persons. The senility rate of 17 is based on 14 persons, which is lower than we anticipated. However, since emphasis was laid on ascertaining the cause of every illness and

disability or the condition by which it might be described, this senility rate, plus the rate for ill-defined and unknown causes in ages over 64, represents the disability rate among persons whose chief trouble was their age.

16. EXTERNAL CAUSES

(Int. List Nos. 165-203)

TABLE 16

Cause	Annual rate per 1,000							
	All ages	0-4	5-9	10-14	15-24	25-44	45-64	65 and over
Total	39.72	28.70	45.62	43.78	32.46	32.52	55.14	46.90
Poisonings	2.78	3.38	4.75	4.67	1.58	2.80	.78	2.47
Burns	2.12	4.50	2.38	2.92	1.58	1.72	1.94	------
Cuts	3.09	3.38	5.23	7.59	3.56	2.58	3.11	1.23
Falls	4.42	2.81	2.85	5.28	1.19	3.23	6.99	12.34
Auto, street railway, etc.	3.39	2.25	3.80	1.17	3.96	3.23	5.44	1.23
Fractures, wounds, and other injuries	21.07	11.82	25.66	21.02	18.61	16.80	31.84	25.92
Other external	2.24	.56	.95	1.17	1.98	2.15	5.05	3.70

It will be noted that practically all of the disabilities resulting from external causes were accidents.

Since practically all of the accidents recorded resulted in some degree of disability, our data include the relatively more serious ones only. "Mere scratches," thumb bruised by hammers, bumps, falls without injury, and the like are not included. The age curve shown in Figure 16 indicates two periods of life in which these disabilities are most frequent—5–14 years of age and in middle age. This is in marked contrast to the usual age curve for mortality from violent causes which is higher among children under 5 years of age than in any age period until old age when it rises precipitately; the frequency of fatal accidents is thus clearly indicated to be greatest at the extremes of life.

It was not practicable to find out sufficient details about each accident to classify all under more refined headings than those given in the table, but the rates for such specific kinds of accidents as burns, cuts, falls, automobile and street-railway accidents are fairly accurate, and are plotted in Figure 17. Cuts and burns are, of course, concomitants of childhood, but they were most frequent in the age period 10–14 years. Falls were also most frequent in that age period, except in the older ages. Three ages of high incidence of automobile accidents are indicated—children 5–9, the age period 15–24, and persons of middle age (45–64), in which age group the highest incidence occurred. Although Hagerstown is a small city (30,000 population in 1922-23), the automobile and street-railway accident rate was 3.4 per 1,000 annually in the population studied.

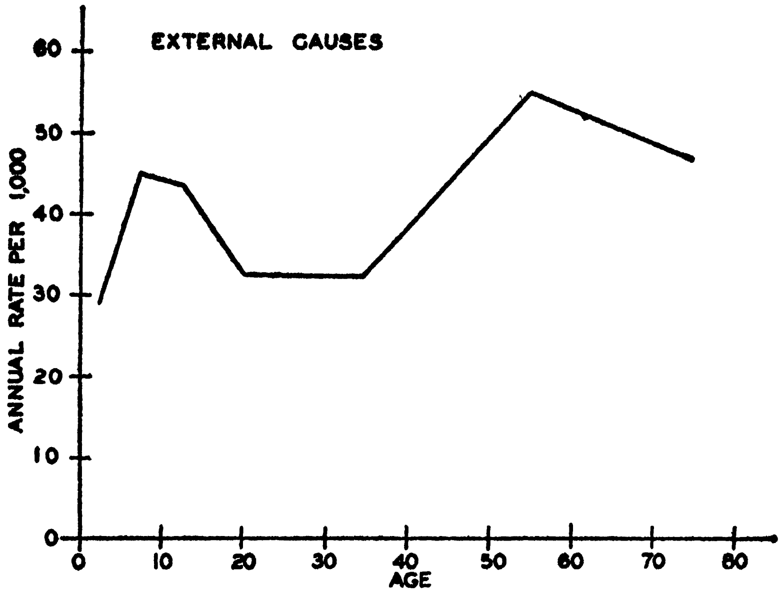

FIG 16 —Incidence of disabilities from external causes among persons of different ages in a white population group in Hagerstown, Md December 1 1921 March 31, 1924

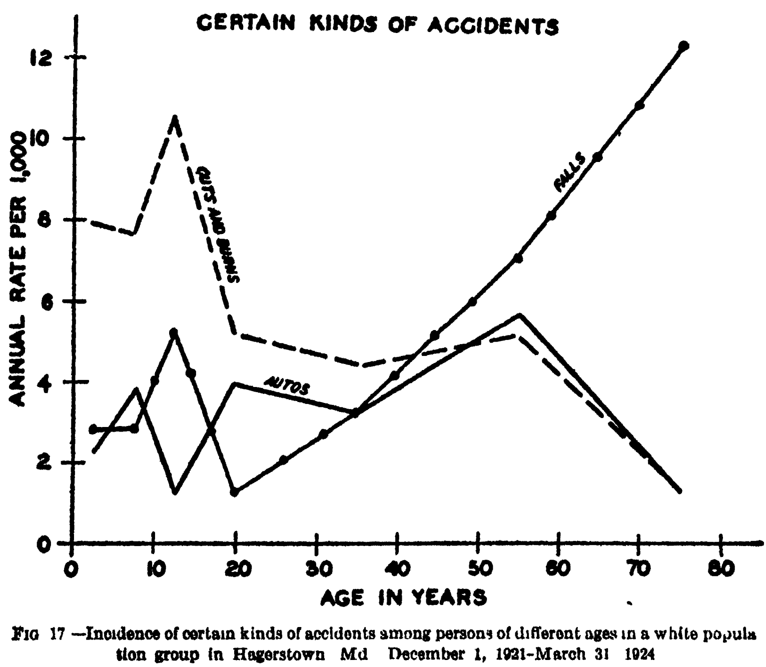

FIG 17 —Incidence of certain kinds of accidents among persons of different ages in a white population group in Hagerstown Md December 1, 1921-March 31 1924

Acknowledgments

The continuous field observations upon which the foregoing report is based were made by the following assistants: F. Ruth Phillips, Mrs. Mary King Phillips, Louise Simmons, Mrs. Clara Bell Ledford, Clarice Buhrman, and Mrs. Alcesta Owen, under the immediate supervision of Passed Asst. Surg. R. B. Norment, jr., Acting Asst. Surg. A. S. Gray, and, later, Surg. C. V. Akin.

In the analysis of the data I am especially indebted to Miss Phillips and to Associate Statistician S. D. Collins and Assistant Statistician Dorothy G. Wiehl, and other members of the statistical staff, as well as to several officers of the Public Health Service for constant advice on medical points.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Chara Fragilis and Mosquito Development. Robert Matheson and G. H. Hinman. American Journal of Hygiene, vol. 8, No. 2, March, 1928, pp. 279–292. (Abstract by L. L. Williams, jr.)

This article records observations made in central New York State from 1923 to 1927. Lake Dryden produced mosquitoes freely, whereas a spring-fed pool, cut off from the lake, did not produce mosquitoes. The pool contained much *Chara fragilis.*

For experimental purposes wooden pails were sunk in the ground, filled with rain water, and baited with dead leaves. *Culex territans* and *Anopheles punctipennis* laid eggs freely in the pails, and the resulting larvæ came through to emergence. Similar pails among the above, but containing *Chara fragilis,* showed some eggs and young larvæ, but none lived to pupate. In one such pail the *Chara* died and subsequently *Anopheles punctipennis* appeared and came through to emergence. The *Chara* apparently controlled breeding as long as it was alive.

Experiments were then conducted using known numbers of *Anopheles punctipennis, Aëdes vexans,* and *Culex pipiens* and *territans.*

Glass aquaria were stocked with earth and stream water and proved excellent rearing pools for mosquito larvæ. Similar aquaria were prepared, but with the addition of *Chara fragilis*. In the *Chara* aquaria nearly all mosquito larvæ died within two days of their introduction therein. All young larvæ died; emergences were only from the pupæ or fourth stage larvæ introduced.

At the beginning of the experiment the water was practically neutral, having a hydrogen ion concentration of pH 7. Soon after the introduction of the *Chara* it rose to pH 7.6 and fluctuated (depending on time of day) between pH 7.6 and pH 9.8. The pH value was lowest between 3 and 5 a. m., and highest between 3 and 4 p. m.

Net cages containing large numbers of larvæ of *Culex pipiens* were placed in the natural *Chara* pool. In all, about twelve hundred larvæ were so placed. Four adults emerged; all of the remaining died.

Dried *Chara fragilis*, in concentration of two to four grams per liter, had a marked effect on larval development. When young larvæ were introduced, they all died within four days. When fourth stage larvæ were introduced into the solution, a few emerged, all being undersized adults; most of them died.

If larvæ are introduced into the *Chara* pool when the pH value is at its highest, the young larvæ are almost immediately paralyzed and death is relatively quick. However, in other aquaria, if the pH value be raised high—not with *Chara*, but with *Oedogonium*—the same pH values can be obtained; but there is no effect on mosquito larvæ, all coming through to emergence. In addition, if water of high pH value be taken from the *Chara* aquaria and put in a separate jar, larvæ added thereto are not disturbed. The authors believe that there is an unstable toxic substance in *Chara*, and that the toxic action is greatest when the pH value is at its highest.

Can B. Coli be Used as an Index of the Proper Pasteurization of Milk? J. C. Swenarton. *Journal of Bacteriology* (1927), v. 13, 419–29. Abstract by W. G. Savage in *Bulletin of Hygiene*, vol. 3, No. 1, January, 1928, p. 20.

"Sixteen Pasteurizing plants were studied with respect to the *B. coli* contents of the Pasteurized milk. The Pasteurizing temperature adopted as satisfactory is 143° F. for 30 minutes with prompt cooling to 40° F. The term *B. coli* is used broadly for lactose-fermenting (with gas), nonsporing aerobes. The test was found to be very helpful in checking up the performances of the different plants.

"The author suggests the following standard: Five quantities, each of 0.1 c. c., to be examined, and of these not more than 20 per cent to show the presence of organisms of the *B. coli* group. Apparently to guard against inequalities of sampling, etc., he adds: 'Occasionally three or more of the five equal 0.1 c. c. portions constituting a single sample may show the presence of *B. coli*. This shall not be allowable if it occurs in more than (*a*) 10 per cent of the standard samples when 10 or more samples have been examined; or in (*b*) one standard sample when less than 10 samples have been examined.' This standard is a more or less arbitrary one, based on the findings from the best plants examined."

Sanitary Production of Ice Cream. R. C. Fisher. *Milk Plant Monthly*, vol 16, No. 3, March, 1927, pp. 98–104. (Abstract by Harriet S. Ryan.)

This paper, which was read at the convention of National Association of Ice Cream Manufacturers, discusses the essential factors in sanitary production of ice cream.

It is the desire of all responsible ice-cream manufacturers to make an ice cream that meets all requirements from a health and sanitary standpoint. There is, however, difference of opinion as to just what is necessary to produce a product that is safe. Some have gone to extremes in taking sanitary precautions, while others have failed to appreciate the importance of certain processes of manufacture. The bacterial content of ice cream is a more valuable measuring stick

of the Pasteurizing process and the sanitary conditions prevailing in the plant than it is in the case of milk. There is some chance for bacterial growth after milk reaches the final package, but no such conditions prevail in the manufacture of ice cream, which is kept in a frozen condition from the time it reaches the can until it is consumed.

The essentials in sanitary production, which are treated in detail in this article, may be summarized as follows: (1) Well-lighted and ventilated building; (2) simple construction of equipment for easy cleaning; (3) Pasteurizing equipment with flush and seepage-proof valves; (4) careful selection and care of ingredients; (5) Pasteurization of the entire ice-cream mix, excepting flavors and fruits, at not less than 50° F. for 30 minutes; (6) cooling and holding of milk below 40° F.; (7) thorough daily cleaning of all equipment; (8) flushing entire system with (*a*) hot water not less than 180° F., or (*b*) flush in freezers with chemical sterilizers; (9) routine bacteriological analysis of mix and ice cream, to determine the efficiency of the above processes; and (10) organization and building up of a strong working force.

Sanitary Control of the Montreal Dairy Company, Ltd. Fifth Annual Report of the Provincial Bureau of Health, Province of Quebec, Canada, 1926–1927, pp. 147-149. (Abstract by I. W. Mendelsohn.)

During the course of the typhoid fever epidemic in Montreal in the spring of 1927, the Montreal Dairy was placed under the absolute sanitary control of the Provincial Bureau of Health chemist. This control lasted from May 21 for 10 weeks, and embodied the following features: (1) Thorough disinfection of both plants of the company. The plant Pasteurizing milk and cream was disinfected twice; (2) continued and frequent examination of all employees of the plants who might come in contact with the products during or after processing or manufacture; (3) removal of all employees suspected of being infected, or who had typhoid in their families, from contact with the products of the plants; (4) maintenance of a close supervision over the raw materials entering the plants to insure that only milk or cream from sources authorized by the city food inspection division of the Montreal Department of Health enters the plants; (5) maintenance of close and constant supervision over every stage of the processing of the milk or cream, or of the manufacture of the ice cream or butter; (6) storage of butter until released upon bacteriological examination; (7) alterations and improvements effected in equipment and methods of processing better to insure the safety of the products; (8) bacteriological examination, at the plant, of the products in various stages of processing; (9) further bacteriological and chemical examinations of various products at the laboratories of the bureau.

A complete report of the epidemic is under preparation.

Refuse Collection and Disposal in Germany. Anon. *The Surveyor*, vol. 73, No. 1882, February 17, 1928, p. 237. (Abstract by H. W. Streeter.)

A review of a report by F. C. Cable, cleansing superintendent of the Westminster City Council, on his observations of methods of collecting and disposing of refuse in German towns, including Cologne, Mannheim, Frankfort, Weidenau, and Hamburg. The review deals mainly with the methods of collection observed.

At Cologne, the refuse was being disposed of by tipping on land 10 miles from the city, though a destructor, then nearing completion, was intended to burn all the refuse of the city. At this and other cities visited, the method of collection involved the use of standard dustbins, distributed to individual householders and collected, usually biweekly, by specially constructed trucks, in some cases equipped with trailers.

At Hamburg, where the Trommel-Wagen system is in operation, about 35 per cent of the refuse goes to a destructor, the remainder being tipped on land. With this system collection vehicles of a new type are used. When these wagons

arrive at the destructor, the bodies are slung off and raised up, the refuse being tipped onto the floor and eventually fed into the furnaces. The system is entirely dustless, and, as far as the design of dustbins and receiving tanks is concerned, Mr. Cable considered it the best system in operation at the time. He recommends its adoption for Westminster. In general, he considers that portions of the Continent are ahead of England so far as methods of refuse collection are concerned, but that the latter is equally ahead of the former in methods of disposal.

Garbage Collection and Disposal. R. W. Stewart. *Pacific Municipalities*, vol. 42, No. 2, February, 1928, pp. 45–48. (Abstract by F. E. DeMartini.)

Due to a lack of intelligent study of garbage handling, some cities dispose of their garbage at considerable expense. Experience of Los Angeles with chemical reduction and with disposal of garbage on a hog farm is described. A land-holding company pays $0.60 per ton for garbage f. o. b. cars Los Angeles, and $1.20 per ton for hauling the garbage to farm, and is still making a profit. Chief cost of garbage collection is caused by labor and delay necessary to enter premises to obtain the garbage. Comparison of collection methods in Los Angeles has shown that for any route within cruising radius of a team, a team is more economical than a motor truck for collecting garbage. On routes with steep grades, motor trucks are preferred. Rubbish collection and disposal are related problems. The value of rubbish lies chiefly in its content of bottles and tin cans.

The Court Rules upon an Exclusive Garbage-Removal Franchise Under an Ordinance Requiring Owner to Separate Refuse and Pay for Removal.[1] Anon. *The American City*, vol. 38, No. 1, January, 1928, p. 183. (Abstract by Harriet S. Ryan.)

A case came up in the Kansas City Court of Appeals in which the plaintiffs unsuccessfully sought to restrain the defendant from removing garbage which the plaintiff had refused to remove. They attempted to justify their refusal under a provision of the ordinance that purported to excuse them from removing garbage that had not been separated, or for persons who had not paid the required fee. The court held that this provision was void. The plaintiffs assumed a right under their franchise by taking into their own hands a method of punishment, where a legal method was provided. An ordinance permitting plaintiffs to refuse to remove garbage and to permit it to remain upon premises would defeat the purpose for which the ordinance was enacted.

Water Purification. P. H. Henderson. *Journal of the Royal Sanitary Institute*, vol. 48, No. 9, March, 1928, pp. 481–483. (Abstract by W. L. Havens.)

This article contains a brief summary of the methods used by the British Army prior to and during the World War in the provision of drinking water. Army units were provided with one of more water carts, the main tank of each cart containing 110 gallons of water. The water was pumped from the source by semirotary pumps through compressed sponge, contained in cylinders, into the main tank and thence through porcelain filter candles into a smaller tank from which the water bottles were filled. It was found that the sponges did not act as efficient clarifiers, that it was impossible to ascertain whether the filter candles were free from flaws or were allowing the passage of bacteria, and that it was difficult to secure a bacterium-proof junction between the candles and the caps of the cylinder to which they were attached. During the war, Sir William Horrocks introduced the use of aluminum sulphate as a precipitant and chlorine as a sterilizing agent. This method, however, had the following objections: (1) In the absence of perfect clarification, chlorine is deviated by the organic matter and either produces unpleasant tastes or is not available to kill the micro-organisms; (2) if excess chlorine is added the strong chlorine taste is extremely

[1] For fuller report of this decision see Public Health Reports, Oct. 21, 1927, p. 2603.

unpleasant; (3) if dechlorination is used, no chlorine is available in case subsequent accidental pollution takes place.

Polluted Water Causes Epidemic. Anon. *Illinois Health News*, vol. 14, No. 2, February, 1928, pp. 42–43. (Abstract by R. E. Tarbett.)

A short description of an outbreak of an intestinal disorder occurring in Marseilles, Ill. The outbreak involved 54 known cases, with an estimated number two to four times that. Epidemiological data implicated the public water supply, which is obtained from artesian wells flowing to a storage reservoir.

Samples of water collected the third morning after the outbreak started showed decided contamination in the water in the distribution system and slight contamination at the pumping station. Upon draining the reservoir, a hole in the bottom of the side wall adjoining a power race carrying polluted Illinois River water was found. This allowed race water to enter the reservoir when the water in the reservoir stood at a lower level than that in the race. An ice jam in the river just before the epidemic occurred had raised the level of the water in the race above normal and above the level of the water in the reservoir.

The Rôle of Ammonia in the Purification of Water. C. H. H. Harold. *Journal Royal Sanitary Institute*, vol. 48, No. 9, March, 1928, pp. 484–488. (Abstract by W. L. Havens.)

During the 1925 maneuvers of the British Army, Major Harold introduced a new method of purifying water. This method consisted in preliminary treatment with ammonia followed by sterilization with chlorine. In this way the absorption of chlorine is restrained and its germicidal powers are enhanced. The sterilizing agent is not unduly deviated by organic matter, and a safe water is produced, practically free from unpleasant tastes. The chlorine solution was given initial contact with the ammonia prior to dosing into water and the highest concentration which did not show evidence of available chlorine was fixed upon as the optimum. Two compounds were produced by the interaction of one equivalent of chlorine with one-half an equivalent of ammonia. In a foul water containing urine and nitrites in unreasonable amount some absorption of monochloramine was evident, but with all casual waters encountered, a dose of 1 p. p. m. has always sufficed. Dichloramine is slower in action, but possesses greater stability than monochloramine. Normally, each water cart having a capacity of 110 gallons is dosed with 1.25 grams of ammonium bicarbonate and about 3 grams by weight of dry chlorine gas.

New Waterworks at Merritton, Ontario. E. H. Darling. *Contract Record and Engineering Review*, vol. 41, No. 52, December 28, 1927, pp. 242–245. (Abstract by R. E. Thompson.)

The water supply of Merritton is obtained from a branch of the Welland Canal above Thorold at Lake Erie level. The turbidity at times is as high as 400 p. p. m. The original supply system consisted of an intake and a settling basin or reservoir of 3,000,000 gallons capacity, the water being delivered by gravity to the town 165 feet below. Owing to ice troubles, augmented by prevailing low water level, a new 18-inch intake, in 18 feet of water, and a pump were installed. When negotiations with neighboring municipalities for the construction of a joint filter plant had failed, it was decided to construct a filter plant, instructions being issued to this effect on February 1. The plant was put in operation in the open on April 23, i. e., in less than 12 weeks' time, the filter house being constructed later. The plant consists of mixing chamber providing 20 minutes' retention period, a coagulation basin providing 3⅜ hours' retention period, four pressure filters of 1½ m. g. d. total capacity, and chlorinating equipment. The total cost was $66,300, and of the filter equipment alone, $12,500. The old settling basin was converted into a filtered water reservoir.

DEATHS DURING WEEK ENDED APRIL 28, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended April 28, 1928, and corresponding week of 1927. (From the Weekly Health Index, May 2, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended Apr. 28, 1928	Corresponding week 1927
Policies in force	71, 066, 816	67, 499, 046
Number of death claims	14, 249	13, 807
Death claims per 1,000 policies in force, annual rate	10. 5	10. 7

Deaths from all causes in certain large cities of the United States during the week ended April 28, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, May 2, 1928, issued by the Bureau of the Census, Department of Commerce)

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 100 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,575,000. The estimated population of the 95 cities reporting deaths is more than 30,960,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended April 21, 1928, and April 23, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
43 States	1,431	1,776	
100 cities	829	1,065	859
Measles:			
42 States	18,550	14,628	
100 cities	8,244	4,638	
Poliomyelitis:			
44 States	19	8	
Scarlet fever:			
43 States	3,936	4,671	
100 cities	1,598	2,154	1,271
Smallpox:			
43 States	1,067	790	
100 cities	135	195	119
Typhoid fever:			
43 States	167	239	
100 cities	38	43	49
Deaths reported			
Influenza and pneumonia:			
95 cities	1,333	1,031	
Smallpox:			
95 cities	1	0	
Louisville, Ky	1	0	

City reports for week ended April 21, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during non-epidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population, July 1, 1926, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported
			Cases, estimated expectancy	Cases reported	Cases reported	Deaths reported

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended April 21, 1928, compared with those for a like period ended April 23, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1927 and 1928, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,050,000 in 1927 and 31,657,000 in 1928. The 95 cities reporting deaths had nearly 30,370,000 estimated population in 1927 and nearly 30,961,000 in 1928. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, March 18 to April 21, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

ARABIA

Aden—Plague.—Under date of April 1, 1928, continued prevalence of plague was reported at Aden, with a total of 1,170 cases and 830 deaths from the outbreak of the epidemic. It was stated that the epidemic had spread to a point 25 miles north of Aden.

CANADA

Fort William, Ontario—Vital statistics and communicable diseases, 1927.—The annual report of the department of health of the city of Fort William, Ontario, Canada, for the year ended October 31, 1927, gives the following statistics:

Population (estimated)	23,544	Death rate per 1,000 births	54.63
Births	604	Deaths (all causes)	[1] 196
Stillbirths	25	Death rate per 1,000 population	[1] 8.32
Deaths under 1 year	33		

[1] Including nonresidents.

Communicable diseases—Cases and deaths at Fort William, Ontario, Canada, year ended October 31, 1927

Disease	Cases	Deaths	Disease	Cases	Deaths
Broncho-pneumonia	8	6	Pneumonia (lobar)		15
Chicken pox	66		Poliomyelitis	1	
Diphtheria	27	2	Scarlet fever	32	
Erysipelas	3		Smallpox	0	
Gonorrhea	51		Syphilis	22	
Influenza	3	1	Tuberculosis	24	12
Measles	32	1	Typhoid fever	10	
Mumps	5		Whooping cough	69	3

Quebec Province—Communicable diseases—Week ended April 21, 1928.—The Bureau of Health of the Province of Quebec reports cases of communicable diseases for the week ended April 21, 1928, as follows:

Disease	Cases	Disease	Cases
Chicken pox	67	Scarlet fever	95
Diphtheria	36	Smallpox	25
German measles	12	Tuberculosis	51
Influenza	6	Typhoid fever	15
Measles	302	Whooping cough	12

ITALY

Messina—Vital statistics—Year 1927.—The following table gives vital statistics for the city of Messina, Italy, for the year 1927:

Population	197,866	Deaths from—Continued.	
Births	4,843	Influenza	86
Still-born	125	Measles	1
Deaths	3,049	Smallpox	1
Deaths from—		Tuberculosis	162
Cerebrospinal meningitis	14	Typhoid fever	27
Diphtheria	19		

MALTA

Communicable diseases—March, 1928.—During the month of March, 1928, communicable diseases were reported in the Island of Malta, as follows:

Disease	Cases	Disease	Cases
Bronchopneumonia	19	Pneumonia	8
Cerebrospinal meningitis	1	Puerperal fever	3
Chicken pox	36	Scarlet fever	6
Diphtheria	4	Trachoma	41
Erysipelas	6	Tuberculosis	28
Influenza	28	Typhoid fever	20
Malta (undulant) fever	46	Whooping cough	6
Malaria [1]	1		

[1] Contracted abroad.

Population, civil, estimated: 228,575.

NIGERIA

Lagos—Plague—Plague-infected rats—February 26–March 3, 1928.—During the week ended March 3, 1928, two cases of plague with two deaths were reported at the port of Lagos, Nigeria. During the same period, of 8,246 rats taken in Lagos, 1,186 were examined, 51 per cent of these being found infected.

Inland localities—Smallpox.—During the same period, 103 cases of smallpox were reported, with 7 deaths, in 12 inland localities of the northern provinces of Nigeria, with high mortality reported at Mokwa. In the southern provinces 7 cases were reported from 3 localities.

Other transmissible diseases.—Ten cases of relapsing fever and 72 cases of trypanosomiasis were reported in the northern provinces of Nigeria.

PORTO RICO

Smallpox—Correction.—The unofficial report of smallpox in the vicinity of Fajardo, Porto Rico, which was published in the Public Health Reports dated March 23, 1928, page 723, was erroneous. The Commissioner of Health of Porto Rico states that smallpox has not been reported there for several years.

UNION OF SOUTH AFRICA

Orange Free State—Plague—Weeks ended March 10 and 17, 1928.—During the two weeks ended March 10 and 17, 1928, three fatal cases of plague were reported on Allemanskamp farm, Theunissen Area of the Winburg District, Orange Free State. A further suspect case, in a native, was reported found on the Theunissen-Theron Road. The case ended fatally.

Smallpox.—A fresh outbreak of smallpox was reported during the week ended March 10, 1928, in the State of Natal.

Typhus fever.—During the week ended March 10, 1928, fresh outbreaks of typhus fever were reported in the Orange Free State, occurring in Harrismith district, and two sporadic cases in Europeans, one of which was imported, in Durban, Natal.

During the week ended March 17, 1928, fresh outbreaks were reported in the Cape Province, occurring in four districts; in Natal, at Port Shepstone; and in the Transvaal, in Potchefstroom district, on a farm.

Month of February, 1928—Typhus fever.—During the month of February, 1928, 65 cases of typhus with 9 deaths were reported in the native population of the Union of South Africa. The distribution of the occurrence was as follows: Cape Province—cases 36, deaths 6; Natal—cases 6, deaths 1; Orange Free State—cases 23, deaths 2. There were reported two cases in Europeans occurring in the State of Natal.

VIRGIN ISLANDS

Communicable diseases—March, 1928.—During the month of March, 1928, communicable diseases were reported in the Virgin Islands of the United States as follows:

Island and disease	Cases	Remarks
St. Thomas and St John:		
Chancroid	1	
Gonorrhea	5	
Malaria	3	2 from St. John. Malignant tertian.
Pellagra	1	
Syphilis	11	
Tuberculosis	1	Chronic pulmonary.
Whooping cough	5	
St. Croix:		
Chancroid	1	
Gonorrhea	10	
Syphilis	5	Secondary.
Tuberculosis	2	Chronic pulmonary.

YUGOSLAVIA

Communicable diseases—March, 1928.—During the month of March, 1928, communicable diseases were reported in Yugoslavia as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Anthrax	27	2	Poliomyelitis	1	
Cerebrospinal meningitis	11	3	Scarlet fever	1,597	276
Diphtheria	224	51	Rabies	1	1
Dysentery	16		Tetanus	18	8
Lethargic encephalitis	1		Typhoid fever	150	10
Leprosy		1	Typhus fever	21	1
Measles	3,932	78			

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen R C WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM

VOL. 43 MAY 18, 1928 NO. 20

THE FULL-TIME COUNTY HEALTH PROGRAM DEVELOPED IN THE MISSISSIPPI VALLEY FOLLOWING THE FLOOD [1]

By J. G. Townsend, *Surgeon, United States Public Health Service*

EMERGENCY SANITATION

The flood caused by the waters of the Mississippi and its tributaries which occurred in the spring of 1927 was one of the greatest and most extensive in the flood history of this river. The following States were flooded: Arkansas, Kentucky, Louisiana, Mississippi, Missouri, and Tennessee. Illinois, to a small degree, also suffered from the effects of the high water.

The total area flooded has been estimated to be nearly thirteen million acres. This represents 20,000 square miles. The number of people affected in this area is estimated at approximately 908,200. With such a large area involved, sustaining a population of nearly a million people, the question of the public health was one of the greatest importance.

In order to care for properly and house the individuals who were forced from their homes, the American Red Cross, with its usual efficiency in such disasters, organized and operated 149 concentration camps in the area, caring for 330,000 people. The distribution of these camps was as follows:

State	Number of camps	Maximum number people cared for in camps	State	Number of camps	Maximum number people cared for in camps
Arkansas	62	133,800	Missouri	18	14,000
Illinois	6	2,500	Tennessee	5	7,300
Kentucky	2	2,200			
Louisiana	33	105,400	Total	149	330,000
Mississippi	23	64,800			

These people were not only housed and fed, but the care of the sick and the prevention of the spread of contagion were also important features of what might be termed the emergency flood-sanitation program, in contradistinction to the permanent post-flood program which was soon to follow.

[1] Presented at the Forty-ninth Annual Meeting of the Louisiana State Medical Society, held at Baton Rouge, La., April 10-12, 1928.

In order to assist the local State health officers and local county health officers in solving these problems, much assistance was received from neighboring States in the furnishing of personnel and biologics. The United States Public Health Service furnished 24 medical officers, 8 sanitary engineers, and 5 scientific assistants, 37 in all. The neighboring States furnished 80 medical officers, engineers, and inspectors. Medical personnel was also furnished by the Rockefeller Foundation. This personnel was detailed only through the requests of the State health officers and was assigned to the State boards of health. Their work consisted in—

(1) Measures toward the safe disposal of excreta through proper latrines in proper locations, properly policed;

(2) Provision of safe water supplies;

(3) The inspection of food and milk supplies furnished concentration camps;

(4) The isolation and quarantine of communicable diseases; and

(5) The immunization against typhoid fever and smallpox.

It has been estimated that in all the States in the flooded area 469,442 individuals were immunized against typhoid fever, receiving three inoculations, and 137,340 individuals were vacinnated against smallpox before the permanent health program began to function about July 1, 1927.

CONTROL OF MALARIA BY MEANS OF SCREENING HOUSES OF MALARIA CARRIERS

This program, developed in the late spring and early summer of 1927, financed by the Red Cross and supervised by engineers of the United States Public Health Service under general supervision of Senior Sanitary Engineer J. A. LePrince, was based on the premise that the major part of any potential spread of malaria would be on the plantations, and that the most effective way of reducing the spread of malaria would be to prevent *Anopheles* mosquitoes from having access to malaria carriers at the farm tenant homes so long as the limited time available and the available funds would allow. The work was organized in Arkansas, Mississippi, Louisiana, and the western portion of Tennessee, this being the first time that so extensive a program had been carried out in this manner.

The plan of procedure was to visit as many homes as possible in the flooded counties to determine whether or not cases of malaria carriers were living there and to screen completely such homes, making them mosquito proof. This was accomplished by inspectors at the time of their visit, who took measurements of doors and sent them to a central point in the State where screen doors were made in conformity with such measurements and shipped to the communities in carload lots. They were hauled to the plantations by

the several plantation owners. The Red Cross assisted the State health departments and cooperating agencies in supplying these inspectors, and also supplied the materials for screening and transportation from the factory to the local communities.

Wire screen was used for all doors and windows with the exception that in some homes a specially prepared netting was used for windows.

The plan of procedure in Louisiana differed from that in other States. Here the State board of health located and listed the malaria carrier farm tenant homes in eight parishes while the assistant State sanitary engineer supervised the construction of screen doors, their shipment, and the installation of all protective screening.

In Arkansas the screen doors were made at the Boys' Industrial School at Pine Bluff; in Mississippi, at Greenwood; in Louisiana, at the State Boys' Industrial School at Monroe, while in Tennessee the manual training department of the public schools at Dyersburg did the work.

This feature of the health program was extensive. The distance from the north to the south end of the entire project was about 320 miles, and the homes to be screened were scattered over 36 counties of four States. Each of the malaria case homes had to be located and the dimensions of the doors taken. In the making of doors about 19 tons of 24-inch sheet steel had to be cut into 337,680 small triangles for screen door reenforcement plates and each triangle had to have holes punched to receive the nails. About 50 miles of 16-mesh wire screen had to be placed on door frames, with a minimum of wastage, in addition to the 7 miles of cotton mosquito bar used on the window frames in some of the counties in Arkansas.

The actual work accomplished in the project was as follows:

	Tennessee	Arkansas	Mississippi	Louisiana	Total, 4 States
Flooded counties in which homes were screened	4	15	9	8	36
Number of homes screened	483	2,348	3,276	653	6,760
Number of doors screened	1,440	7,304	10,238	2,193	21,175
Number of windows screened	2,387	12,200	12,931	2,777	30,295
Average cost of screening a farm-tenant home	$11 66	$9.67	$11 07	$13 99	$11.02
Total cost	$5,630.87	$22,707.35	$36,254.39	$9,883.00	$74,475.60

NOTE.—This table is taken from the report of Senior Sanitary Engineer J. A. LePrince, United States Public Health Service.

The labor cost of making these doors was about 27 cents per door, the average total cost of each door complete being about $1.40. It is realized that all homes with malaria carriers were not screened—only a proportion were; but the fact that nearly 7,000 homes were screened in a period of approximately 90 days is a good start, especially when it is recognized that, so far as it was possible to determine,

these homes represented places where malaria cases resided, and that the number of families containing malaria cases capable of infecting others is but a small proportion of the surrounding farm homes in the vicinity.

The work of further extending the screening program now rests with the full-time county health units, the creation of which was the last step in the flood health program, or which might more properly be termed the post-flood program.

FULL-TIME COUNTY HEALTH UNITS DEVELOPED AS A RESULT OF THE FLOOD

The programs just discussed might be properly termed actual emergency programs, which, of course, were limited to immediate needs; but a time came when the strictly emergency work was curtailed or discontinued as the situation was relieved. It was recognized, however, that a serious problem still existed. In the majority of the flooded counties there were no organized public health agencies to carry on to a logical conclusion the preventive measures started and slight prospects of developing a program, as the counties affected had very little money to appropriate for this work, in some instances being in actual financial straits.

It has long been recognized that the best public health program, and one that will best insure permanency, is the full-time county health unit plan, the community served enjoying the services of a full-time director, full-time nurse, and full-time sanitary inspector. Some communities have more personnel, some less, but that is the standard.

At a meeting in New Orleans in June, 1927, attended by representatives of the Public Health Service, of the Rockefeller Foundation, of the American Red Cross, and of various State boards of health, it was recognized and agreed that some such plan should be formulated and such a program fostered in the so-called flooded counties. This was made possible by a liberal contribution from the Public Health Service and the Rockefeller Foundation, supplementing county and State funds, the counties being asked to appropriate a very small part of the total budget necessary to finance the health units. It was agreed that this fiscal plan would be in operation for an 18-month period from July 1, 1927, to January 1, 1929.

Representatives of the Public Health Service and of the Rockefeller Foundation assigned to the various State boards of health assisted the State health departments in laying this proposition before the various county officials and organizing the programs adopted. Of the 103 counties considered flooded in the six States, 85 were visited, and this plan was presented to the local governing authorities. The result was encouraging in that 67, or 78 per cent, signed the budget and definitely committed the county funds to the project as of October 31, 1927.

Since the October figures were compiled four additional flood parishes of Louisiana have adopted the full-time plan, while two more committed to the project were organized. These six parishes started to function on the first of the year. This gives Louisiana 19 parishes organized on a full-time health plan since the flood.

The total number of counties adopting the full-time plan to date, including those in which no county funds were committed, is 78, or about 92 per cent of the total with which contact was made. There were a few counties that actually had no money whatever to put into a health project, and in these the United States Public Health Service, the Rockefeller Foundation, and State boards of health financed the projects temporarily with a limited personnel. In many counties the work was made possible by donations from the local Red Cross chapters, municipalities, chambers of commerce, and civic organizations.

As is generally the case in the organization of full-time health units, a difficulty of no mean proportion was that of finding suitable trained personnel to carry on the work. In order to meet this difficulty and facilitate the speeding up of the program, the Rockefeller Foundation organized training schools for the practical teaching of field public health work to prospective health officers, nurses, and inspectors. The principal school was located at Indianola, Miss. Without exception the States developing the full-time rural program sent trainees to this school. The Rockefeller Foundation approved the training of the candidates upon request of the various State boards of health. Those accepted were given a grant of their railroad and Pullman fare from their homes to the training school and return to the new field of duty, as well as a per diem allowance while en route and at the school. The number of trainees sent to the school, as of March 15, 1928, is given in the following table:

State	Physicians	Nurses	Inspectors	Total	State	Physicians	Nurses	Inspectors	Total
Arkansas	20	23	17	60	Missouri	0	0	7	7
Kentucky	10	29	16	55	Tennessee	1	0	0	1
Louisiana	13	7	24	44					
Mississippi	4	12	19	35	Total	48	71	83	202

Not all of these trainees were placed on duty, owing to failure to qualify and to resignations. On the other hand, some were appointed without being sent to the school. This does not include the 24 office clerks on duty as of October 31, 1927.

The Rockefeller Foundation submitted an appraisal on each trainee which was of inestimable value to the State boards of health in determining the fitness and ability of the persons seeking these positions.

The public-health programs adopted in these full-time projects were along the same standard lines as elsewhere enjoyed. In brief, activities were directed toward safeguarding the health of the child from before birth to adolescence, through the medium of prenatal hygiene, infant hygiene, preschool and school hygiene. This was accomplished through group conferences or clinics, and the intensive physical inspection of school children for the purpose of locating physical defects and advising the parents to have corrections made through the family physicians. Concomitant with this program were educational measures in newspaper articles, lectures, and the distribution of pamphlets. The local profession was encouraged to report communicable diseases and proper steps were taken toward isolation and quarantine. Prevention of soil pollution was effected by having sewer connections made when possible and the construction of the vault type of sanitary privy, through personal persuasion and the enforcement of the existing ordinances. The inspection of food and milk supplies, vaccination against smallpox, and inoculation against typhoid fever and diphtheria were also stressed and emphasized. A résumé of the work of these full-time projects in the Mississippi Valley from July 1, 1927, through the month of February, 1928, is given in the list below.

Résumé of the work of the full-time projects in the Mississippi Valley from July 1, 1927, through February 29, 1928

NOTE.—These figures present the public-health activities carried on in the newly organized counties and parishes from July 1, 1927, to date, and do not include any activities carried on in the 18 full-time county health projects in the several States which were organized and functioning before the flood. It must also be remembered that many of these counties were not organized and operating until the late fall of 1927, while some were not organized until the first part of 1928

1. EDUCATIONAL:	
(a) Lectures	5, 152
(b) Attendance	166, 996
(c) Bulletins distributed	201, 361
(d) Newspaper articles	5, 807
(e) Circular letters	38, 229

(c) For lunacy	112
(d) Of prisoners	847
(e) Of food handlers	266

5. ACUTE COMMUNICABLE DISEASE CONTROL:	
(a) Visits to cases, carriers, contacts or suspects	11, 673
(b) Cases or carriers isolated or quarantined	5, 831
6. VENEREAL DISEASE CONTROL:	
(a) Suspects examined	1, 191
(b) Prophylactic treatments	48
(c) Curative treatments	1, 675
7. TUBERCULOSIS CONTROL:	
(a) Number examined	775
(b) Positive	170
(c) Negative	269
(d) Placed in institutions	232
(e) Home visits	1, 132
8. PERSONS TREATED FOR REMOVAL OF HOOKWORM	18
9. PERSONS TREATED FOR PREVENTION OR CURE OF GOITER	16
10. SCHICK TESTS	4, 075
11. COWS TUBERCULIN TESTED	3, 587
12. IMMUNIZATION:	
(a) Complete antityphoid administrations	91, 173
(b) Antismallpox vaccinations	42, 045
(c) Complete diphtheria toxin-antitoxin administrations	30, 843
(d) Persons given prophylactic diphtheria antitoxin	640
(e) Persons given antirabic treatment	74
13. CHILD HYGIENE:	
(a) Prenatal—	
(1) Cases given advice	881
(2) Examinations	266
(3) Office consultations	769
(4) Group conferences	120
(5) Home visits	1, 287
(6) Midwives instructed	2, 725
(b) Infant and preschool—	
(1) Babies and children examined	4, 371
(2) Office consultations, mothers	2, 385
(3) Group conferences with mothers	467
(c) School—	
(1) Children examined	113, 394
(2) Found defective	69, 453
(3) Defects found	136, 030
(4) Consultations, parents (office and school)	3, 547
(5) Home visits	18, 098
(6) Talks to classes or drills in hygiene	4, 769
(7) Exclusions for communicable disease	2, 620
(d) Nutritional classes—	
(1) Cases attending	3, 352
15. LABORATORY EXAMINATIONS:	
Specimens—	
Blood for Widal	118
Blood for *B. typhosus*	20
Blood for Wassermann	1, 654
Blood for malaria parasite	4, 791
Smears for *B. diphtheriae*	2, 314
Smears for *gonococci*	260
Sputum for *B. tuberculosis*	446

15. LABORATORY EXAMINATIONS—Continued.

Specimens—Continued.	
Feces for parasites	1, 015
Water for *B. coli*	1, 453
Milk for high bacterial content	255
16. RESULTS:	
1. Sanitary privies installed—	
(*a*) Septic or L. R. S	58
(*b*) Water-tight vault	9
(*c*) Bucket and box	38
(*d*) Pit	9, 037
2. Privies restored to sanitary type	1, 210
3. Septic tanks installed	138
4. New sewer connections	1, 659
5. New water connections	336
6. Wells or springs improved	2, 556
7. Public milk supplies radically improved	178
8. Public food handling places radically improved	867
9. Places producing foods for sale radically improved	196
10. Dwellings effectively screened against flies and mosquitoes	2, 524
11. Stables made sanitary	56
12. Nuisances corrected	2, 505
13. Convictions for violation sanitary laws	5
14. Nutritional cases improved	688
15. Corrections of physical defects induced:	
(*a*) In infants; (*b*) In preschool children; (*c*) In school children; (*d*) In adults	10, 241

MEASURES TAKEN IN THE CONTROL OF PELLAGRA

The diseases which showed the greatest increase during the post-flood period were pellagra and malaria. A definite increase in the pellagra rate was shown on the morbidity reports submitted from the six States, with the exception of Missouri and Kentucky. The greatest increase was shown in the State of Mississippi, where there were reported approximately 6,000 cases in the four months' period July to October, 1927, inclusive. Only 2,800 cases were reported for the corresponding period in 1926. A marked increase in the pellagra rate was also experienced in Arkansas.

The only measures taken to combat the increase in pellagra were through the medium of the distribution of dried brewers' yeast, which was generously supplied by the American Red Cross to various State boards of health. This was distributed through the full-time health departments, which, in turn, in many instances, utilized the farm demonstration agents and other local organizations. In some instances tomato juice in a limited amount was also distributed.

MALARIA CONTROL

In the control of malaria, emphasis was placed on the continuance of the screening program previously discussed. Although the later work was not done free of cost to the owners of homes, at the same time the comfort of properly screened houses was amply demonstrated, and it is believed that a renewed interest in this phase of malaria control is developing. From the reports submitted by Mr. LePrince on the results of the screening program of last summer it was learned that in some instances county health officers have demonstrated at county agricultural fairs how substantially made screen doors can be constructed by farm tenants. In two parishes in Louisiana the health officers undertook a project which includes the screening of all malaria families in his parish. In other States the work is under way for the protection by the screening of all malaria homes in malaria counties. (Work is now (March 19, 1928) going on in six counties of five States as reported by Mr. Le Prince.)

The free distribution of quinine in the form of capsules, pills, and tablets was also carried out by the full-time health departments through the medium of local organizations, quinine being furnished by the American Red Cross. At the present time, however, the Red Cross has retrenched considerably in its policy of supplying this commodity as well as yeast in the control of pellagra.

CONCLUSIONS

While deploring the frightful disaster of last spring, some comfort may be obtained in the knowledge that better communities are builded on the ruins of those destroyed, and, as a rule, a better public-health régime may be inaugurated. Surely in this experience there has developed another flood—a flood of sanitation development which has placed us many years ahead of our old program of full-time county health service. The fact that since July, 1927, 78 counties have joined the roll of those that are enjoying adequate public-health protection through the labors of over 200 full-time health workers is a distinct step forward and a stimulus to perpetuate these endeavors. This can be done only by creating such a popular demand for full-time health protection that it will merit the same consideration in local government as an "educational program" or a "good-roads program."

It is not too much to believe that this will be accomplished and that the Mississippi Valley will enjoy the universal public-health protection it deserves.

REGULAR SESSION OF THE PERMANENT COMMITTEE OF THE INTERNATIONAL OFFICE, NOVEMBER 7–16, 1927 [1]

The Permanent Committee of the International Office of Public Hygiene held its regular session of 1927 from November 7 to 16, at Paris.

There were present: Messrs. Velghe (Belgium), President; Madsen (Denmark), Shahin Pacha (Egypt), Pulido (Spain), Taliaferro Clark (United States of America), Barrére (France), L. Raynaud (Algeria), Duchêne (French West Africa), Audibert (French Indo-China), l'Herminier (Madagascar), G. S. Buchanan (Great Britain), R. A. Needham (British India), C. L. Park (Australia), Le Noblet du Plessis (Canada), S. P. James (New Zealand), P. G. Stock (Union of South Africa), Mataraugas (Greece), Lutrario (Italy), Mitsuzo Tsurumi (Japan), Praum (Luxemburg), Colombani (Morocco), Roussel-Despierres (Monaco), H. M. Gram (Norway), N. M. Josephus Jitta (Netherlands), W. de Vogel (Netherlands Indies), Mimbela (Peru), Djavad-Asthiany (Persia), W Chodzko (Poland), Ricardo Jorge (Portugal), Ionesco-Mohaesti (Rumania), Yoannovitch (Kingdom of the Serbs, Croats, and Slovenes), O. F. H. Atkey (Sudan), C. Kling (Sweden), H. Carriére (Switzerland), D. Prochazka (Czechoslovakia), de Navailles (Tunis), Roubakine (Union of Soviet Socialist Republics), Herosa (Uruguay), also Mr. Pottevin, Director of the International Office of Public Hygiene.

On report of the director, and in conformity with the proposals of its special commission of experts, the committee interpreted some points which might be raised in regard to certain articles of the International Sanitary Convention, as well as the details of the functioning of the services of notifications.

It also adopted the final model of the certificate of deratization or exemption from deratization provided in article 28 of the convention.

As concerns the use of wireless in quarantine operations, the committee was of the opinion that it was advisable to confine itself, for the time being, to establishing a code form which could be adopted uniformly by all countries and in accordance with which communications could be made by the ship to the port authority. This would facilitate, to a considerable extent, the introduction of declaration by wireless communication into quarantine practice. Only by actual use and by taking into account the special conditions peculiar to each country can we estimate the facilities which would be accorded to vessels on the faith of these declarations.

[1] Translated from Revue d'Hygiène et de Médicine Préventive, Vol. L, No 3, March, 1928

The question appears, moreover, to be closely connected with that of the qualifications of, and other questions concerning, ships' surgeons. This subject has again claimed the attention of the committee, which continues to carry on the inquiry undertaken in the several countries.

The committee has received from the Director of the Pan American Sanitary Bureau, at Washington, the official notice that the Pan American Sanitary Conference which met at Lima in October, 1927, adopted a resolution according to which the said Bureau at Washington assumes the obligations of a regional bureau under the terms of the International Sanitary Convention.

The arrangement regulating the methods of cooperation between the Pan American Sanitary Bureau and the International Bureau of Public Hygiene will be submitted to the committee at its next session in May, 1928.

The President of the Maritime Sanitary and Quarantine Council of Egypt, taking part in the sessions of the committee, presented the plan of arrangement established in agreement with the Director of the Office, according to the terms of which the council shall function as regional bureau for the Near East, and, responsible to the International Office, shall exercise for its dependent countries the duties imposed upon it by the International Sanitary Convention. This proposal was adopted. It had previously received the sanction of the Maritime Sanitary and Quarantine Council.

The Office has published, in its monthly *Bulletin*, the portions of the Report on the International Sanitary Conference of the Pacific (Melbourne, 1926) which are of special interest from the epidemiological point of view. On invitation of the Australian Government an international sanitary commission is to study on the spot the epidemiology of the South Pacific. The Office will be enabled to follow the work.

The committee has received and examined the first of the monographs which are to be established, for each country, in carrying out the provisions of several articles (notably articles 14, 28, and 50) [relating to rat conditions at ports, deratization of vessels, and port sanitary equipment] of the International Sanitary Convention, and which will be published by the Office under the form of an international maritime sanitary annual. These first monographs relate to Great Britain (England and Wales), France, and Morocco.

Examination of these documents has made it possible to present specifically a certain number of suggestions which will be useful in giving to the complete publication the character which will best respond to the spirit of the convention.

The Office is collaborating with the League of Red Cross Societies in the preparation of a form of medical instruction for captains of

vessels not having a doctor on board, which can be adopted as an international document. This instruction should include a section relative to hygiene, and to the prophylactic measures the observance of which is of capital importance to prevent the diffusion of epidemic diseases from one country to another by maritime route, and thus falls directly into line with the objects had in view by the International Sanitary Convention.

II

The committee has received a communication of the resolutions adopted at the last session of the Health Committee of the League of Nations, held at Geneva, October 28 to November 3, 1927.

It has examined the technical report of the commission of pharmacological experts which it had charged with the study of propositions made by the Governments relative to preparations, included in the several pharmacopœias, which there might be occasion to withdraw from the provisions of the opium convention of Geneva of 1925, by application of article 8 of the said convention, by reason of the fact that narcotics were there associated with other substances, making abuse and the establishment of addiction impossible. It has approved the conclusions of this report, which will be transmitted to the Health Committee of the League of Nations. Moreover, the same committee has made a new demand to be informed whether the provisions of the opium convention of Geneva should be made applicable to certain products—dilaudide, benzoyl-morphine, and eventually the ethers derived from morphine.

III

The recent epidemics, happily circumscribed, of yellow fever in West Africa and of cholera in Iraq, have given a timely interest to the discussions on yellow fever and cholera. Both have been the subjects of documentary reports, cholera, after deep study made on the spot.

The extension of yellow fever in French West Africa has been closely observed: In 1926, there were 53 cases in Senegal, 2 in Dahomey, 2 in the Upper Volta; in 1927 (latter part of May to mid-October), there were 151 cases in Senegal, of which 104 were followed by death. Syrians, recently arrived in the Colony, were especially attacked; among them there were 25 cases in 1926 and 31 cases in 1927, in a total of 1,000. Living under bad health conditions and rejecting precautions recommended against the bite of mosquitoes, they also showed the sensitiveness to the virus observed generally in the newly arrived. Yellow fever should be considered an endemic disease in West Africa. The native population has to a large extent acquired a spontaneous immunity; the virus is conserved by abor-

tive cases in young children. The arrival of groups of Europeans has frequently, in the history of the disease, been the occasion of epidemic revival. The menace of extension to North Africa and the Mediterranean Basin does not for the moment appear to exist. Classic prophylactic measures and a strict surveillance have been instituted. The data concerning French West Africa, from which cases of yellow fever are regularly reported to the International Office of Public Hygiene, will be completed by the time of the next session by analogous information from the English, Spanish, and Portuguese possessions in West and Equatorial Africa, and the Belgian Congo.

An exchange of views on the subject of the actual status of the question of the pathogenic germ of yellow fever has brought out that the question remains open.

Cholera appeared at the end of July in ports of the upper Persian Gulf—Abadan, Basra, and Mohammerah. The energetic defensive measures taken immediately by the sanitary authorities of Iraq, Syria, Palestine, Egypt, and Persia, prevented its propagation along the land and river routes of travel. In Iraq it did not pass Remaldi on the Euphrates or Baghdad on the Tigris (where there were only four imported cases and one case of local origin). In Persia, it followed the river Karoun to the Dizfould region. The epidemic is now terminated; for Iraq there were 1,038 cases with 756 deaths. Strict quarantine services were established along the danger routes and anticholera vaccination was required of every person going into a neighboring country. This vaccination was very largely practiced in the infected localities, notably in Persia in 40 per cent of the menaced population. The transmission of the infection by merchandise such as dates shipped from Basra was recognized to be impossible after experimental verification.

Indo-China was severely attacked in 1926 by cholera, which prevailed in all the countries of the Union. The number of deaths reached about 15,000. The epidemic is almost at an end. It would have been much more severe but for the extensive employment of anticholera vaccination, which was performed on more than 2,000,000 persons, or more than one-tenth of the population. The proportion of deaths among the vaccinated in Cochin China was 0.79 per 10,000.

Vaccination, either by subcutaneous injection or ingestion of bile vaccine, gave very encouraging results in British India. The research undertaken in that country on the agglutinability of authentic cholera vibrios and vibrios originally nonagglutinable has shown that the first may lose and the second acquire the property of being agglutinated by anticholera serums.

Facts suggesting new problems on the subject of the epidemiology of plague have been reported. It has been agreed up to the present time to attribute a rôle almost negligible to the domestic mouse;

its habitual flea does not seem capable of inoculating with plague virus. But the coincidence of an epizootic of mice and a series of human cases has recently been proved at Oran; on the other hand, in the sandy regions of South East Russia, fodder sometimes conceals numerous cadavers of plague mice which might contaminate man either directly or by the intermediary of camels infected by them. In the same endemic focus a plague carrier has been observed who has planted the contagion around him; and facts more or less analogous have been noted in Algiers and Senegal. It is important to determine definitely for the future whether there exist septicemic forms of latent plague without symptoms and without fever, which would lend themselves to contamination of the vicinity by the intermediary of fleas. It is to such forms that the term "germ carriers" would apply; on the other hand, a bubo without vital reaction is only an abortive form of the disease, and the bacilli which it may harbor appear but slightly susceptible of being disseminated. Finally, the conservation of virulent plague bacilli in the body of the flea, outside its host, has been stated for periods of 3 to 4 months (Union of South Africa), and even 10 months (South East Russia).

The methods of estimating the numbers of rats infesting ships have been studied experimentally at Liverpool. The best basis has appeared to be the enumeration of the droppings, with the reservation that these may be very abundant in spite of there being a small number of rats, and that the quantities vary largely under influence of the alimentary régime of the animals. Nevertheless, the observations made at the quarantine station at the port of New York have shown that, when the authorities have imposed fumigation of vessels guided principally by the amount of droppings discovered, an average of 20.5 dead rats per ship was recovered, whereas in the cases where fumigation was not required only 1.29 per cent of dead rats was found per ship.

Smallpox and antismallpox vaccination very actively preoccupy the health authorities in various countries, and the problems discussed have been many. There seems to exist at present, side by side with grave classic smallpox, a benign type, or "alastrim" (Switzerland, Great Britain), the character of which does not seem to justify the onerous measures of vaccination and especially of isolation which continue generally to be applied to it. Is this type definitively fixed, or is the attenuation of its virus reversible? The desire to reduce to a minimum the prejudices of the public in regard to vaccination has led the United States to study the possibility of limiting the vaccinal field—affirming that the duration of immunity is not in proportion to the dose of vaccine inoculated, employing the multiple pressure method of vaccination, and presenting a mass of practical details.

Post vaccinal encephalitis appears to-day to have struck the Netherlands more than any other country. It is not connected with the virulence of the vaccine, for it has remained practically at the same rate in spite of the employment of slightly virulent stock or of neuro-vaccine; on the other hand, a virus activated by passage through the rabbit has not caused a single case of encephalitis out of 100,000 vaccinations. There seems to exist a family susceptibility; and, on the other hand, for the same number of vaccinations, 16 cases of encephalitis were observed in January-February and none in November-December. The hypothesis of a relation with lethargic encephalitis is being more and more abandoned; besides, post-vaccinal encephalitis is cured without sequellae. A remarkable fact has been brought to light by these discussions; Italy and Japán have not had a single case of post-vaccinal encephalitis; and in those countries vaccination is obligatory in the course of the first year. Other observations concur in justifying the opinion that vaccination of the child is most inoffensive when it is done early.

Poliomyelitis has prevailed with unusual intensity during recent years in England, Switzerland, in 1927 in Rumania, Saxony, and Canada. The cases have been, in general, very much disseminated, although there have been some true foci. The abortive and non-diagnosed forms are as numerous as the clinical cases, or more so, and transmit the virus. Prophylaxis by convalescent serum has given remarkable results in Sweden; also, treatment by an experimental serum in Rumania.

The treatment of general paralysis by inoculation of malaria continues to be closely followed by the sanitary administration in England, where 1,400 cases have been treated. It has been studied in Rumania; also, the frequency of general paralysis in relation with that of paludism in Spain.

Organizations for maternal and child welfare have been established in the United States, Greece, Union of Soviet Socialist Republics, Japan, and Switzerland. In this latter country, infantile mortality has declined from 125 per 1,000 live births in 1906 to 55 in 1926. However, the gain does not relate to stillbirths nor to the first four days of life, which still indicate insufficient protection of the mother during pregnancy and at the moment of delivery.

Finally, the following questions have been touched on, especially as continuations of former discussions or as preparations for work to come: The antiseptics and coloring matters in alimentary substances; the prevention of beriberi in the Netherlands Indies by condensed vitamin B; the legal prescriptions concerning scarlet fever streptococcus toxin and antitoxin in the United States; the vaccination of

the adult by BC-G ["Bacille Calmette-Guérin"] in Norway; the antivenereal program in Japan; the control of medicines in Japan; the antileprosy organization and relief of lepers in the United States; cancer in the natives of North Africa; social aid to seamen of the merchant marine and social aid for the tuberculous in Italy; social aid in Japan; the High School of Malariology of Rome; School of Hygiene of Warsaw.

In closing the session the President recalled that the International Office of Public Hygiene, created by the International Arrangement concluded at Rome December 9, 1907, has now had 20 years of existence. Conformably to the intentions of the Governments that instituted it, it has achieved a permanent bond among the countries signatory to the international sanitary conventions and has not ceased to promote and control the combat against "pestilential diseases." At the same time, while enlarging more and more the circle of its activities, it has widely and effectively concerned itself with the problems, often very diverse, relative to diseases in the case of which social action, and especially concerted action, may contribute to the preservation of populations.

DEATH RATES IN A GROUP OF INSURED PERSONS

Rates for Principal Causes of Death for March, 1928

The accompanying table is taken from the Statistical Bulletin for April, 1928, issued by the Metropolitan Life Insurance Co., and presents the mortality experience of the industrial insurance department of the company, by principal causes of death, for March, 1928, as compared with February and with March, 1927. The rates are based on a strength of more than 18,000,000 insured persons in the United States and Canada.

The health of this group of persons during March, as reflected in the death rate, continued favorable, the rate being the minimum for this month, 10.3 per 1,000, the same as that recorded in March of last year. There occurred the expected seasonal rise from the rate for February, 9.4 per 1,000, which was due, for the most part, to higher mortality from influenza, pneumonia, tuberculosis, heart disease, and Bright's disease.

As compared with March of last year, declines are shown for three of the four principal epidemic diseases of childhood—measles, scarlet fever, and whooping cough—for typhoid fever, and for tuberculosis, cancer, diarrhea, and enteritis, puerperal causes, suicides, homicides, accidents, and automobile fatalities. The death rate for tuberculosis was 100.1 per 100,000, as compared with 114.4 for March last year,

which was the previous minimum rate for this month. The Bulletin states:

This low rate for tuberculous disease is one of the best measures of the success which has attended the campaign against tuberculosis in America. It should be remembered that March and April are the months which register the maximum death rates for tuberculosis year after year, whereas the lowest are almost always recorded in September. Only eight years ago—that is, in March, 1920—the tuberculosis mortality rate among the industrial policyholders was 178.7 per 100,000 and the September figure was 116.1. Thus the death rate in 1928, *in the month of highest mortality*, has actually declined to a point below that recorded only eight years ago in the month of lowest mortality.

On the other hand, considerably higher rates this year than last are shown for heart disease, pneumonia, and Bright's disease, and slight increases for influenza, diabetes, cerebral hemorrhage, and respiratory diseases other than pneumonia.

Death rates (annual basis) for principal causes per 100,000, March, 1928, as compared with February and with March, 1927

[Industrial insurance department, Metropolitan Life Insurance Co.]

Causes of death	Rate per 100,000 lives exposed [1]			
	March, 1928	February, 1928	March, 1927	Year 1927 [2]
Total, all causes	1,027.0	943.5	1,028.5	885.4
Typhoid fever	1.3	1.7	3.0	4.6
Measles	7.7	4.2	7.9	4.1
Scarlet fever	3.4	4.4	4.9	3.1
Whooping cough	6.2	4 1	8.3	6.4
Diphtheria	11.4	12.6	11.3	10.5
Influenza	34.8	25.6	32.3	17.7
Tuberculosis (all forms)	100.1	89.5	114.1	93.3
Tuberculosis of respiratory system	88.6	78.6	100.3	81.7
Cancer	74.8	76.3	77.2	74.0
Diabetes mellitus	20.4	18.6	19.2	16.7
Cerebral hemorrhage	59.6	57 9	58.9	54.9
Organic diseases of heart	160.7	149.4	149.4	132.2
Pneumonia (all forms)	137.3	117.4	119.9	77.6
Other respiratory diseases	21.9	18.2	19.9	15.4
Diarrhea and enteritis	14.7	14.0	16.3	24.5
Bright's disease (chronic nephritis)	82.3	75.5	79.6	69.3
Puerperal state	13.8	13.3	17.2	15.4
Suicides	9.3	7.0	9.9	8.3
Homicides	6.2	5.6	8.1	7.2
Other external causes (excluding suicides and homicides)	48.3	55.6	55.9	63.7
Traumatism by automobiles	11.2	15 8	12.3	18.3
All other causes	212.5	192.6	215.0	186.7

[1] All figures include infants insured under 1 year of age.
[2] Based on provisional estimate of lives exposed to risk in 1927.

COURT DECISION RELATING TO PUBLIC HEALTH

Compensation for tuberculosis allowed under workmen's compensation act.—(Ohio Court of Appeals; Industrial Commission *v.* Rice, 160 N. E. 484; decided June 6, 1927.) An employee was incarcerated in a furnace by a falling door, and for a period of three minutes breathed heated fumes and gas from oil which had been burned as a fuel

therein. He was thereafter physically incapacitated to perform labor, and later tuberculosis resulted. Claim was brought under the workmen's compensation act but was disallowed by the State industrial commission on the ground that the disability was not due to an injury. On appeal to the court of common pleas compensation was awarded. The commission carried the case to the court of appeals, which said that the court of common pleas "was warranted in finding that the incapacity to work and the tuberculosis resulted directly from injury caused by inhaling such injurious substances, and that such finding is not manifestly against the weight of the evidence." The appellate court held that the tuberculosis and any other disability caused by the fumes and gas were compensable.

PUBLIC HEALTH ENGINEERING ABSTRACTS

The Effect of Various Chemicals on the Spreading and Penetration of Oils in Different Mosquito Breeding Places. Joseph M. Ginsburg. Proceedings of 14th Annual Meeting of the New Jersey Mosquito Extermination Association, 1927. (Abstract by L. L. Williams, jr.)

The author emphasizes the need for increasing the spreading power of oils and of increasing spread and toxicity of the cheaper fuel oils.

He recounts the theories of the mechanism of "spread" as put forward by Harkins and by Langmuir, which ascribes the spreading power to the presence of either active (or polar) groups (such as OH, COOH, etc.), or double bonds in the hydrocarbon chain. Such a double or triple bond acts similarly to a polar group (OH, etc.), and is attracted by water and, hence, causes "spreading." The author concludes that, therefore, an oil containing unsaturated hydrocarbons should spread more rapidly than an oil free from these hydrocarbons. Tests confirmed his theory.

He tested varying percentages of 35 compounds and had greatest success with monohydric alcohols, phenols, cresols, xylenols, pine oils, and turpentine. Of these, the cresols proved best both as to spreading power and toxicity.

Using fuel oil as a testing medium, the most effective mixture was made by adding 1 per cent cresylic acid. This spread 1½ times as much as plain fuel oil, penetrated among weeds and flotage, and killed larvæ within half an hour. On sewage beds, 3 per cent cresylic acid was necessary to produce larval death within half an hour, whereas pure kerosene took twelve hours. After kerosene, breeding was resumed in less than 3 days; after fuel oil with cresylic acid, no signs of breeding were seen after 3 days.

The mixture of 1 per cent cresylic acid with fuel oil was tried with uniform success on pools, ditches, vegetation-covered ponds, cattail swamps, and salt marsh areas. It increases the cost of the oil less than 1 cent per gallon.

A Container for Field Collection of Mosquito Larvæ. Wm. A. Hoffman. *Science*, vol. 66, No. 1716, November 18, 1927, p. 484. (Abstract by L. M. Fisher.)

The container consists of a 4-ounce jar with a two-holed rubber stopper, through which two glass tubes are passed, one flared, funnel shaped, through which the larvæ can be passed. A metal clamp is fitted tightly to the neck of the jar by means of a tension spring. One end of the clamp hooks over the carrier's belt.

It is stated that fairly satisfactory results were obtained over a period of four months' use in Porto Rico.

(Abstractor's note: A large percentage of larvæ were drowned in containers somewhat similar to the one described when carried about on the person during collection trips in some of the Southern States. Better results were obtained by carrying larvæ on moistened blotting paper or cotton in a suitable container permitting a certain amount of evaporation to keep the larvæ cool.)

Some aspects of house fly control. D. W. Wallace. *Health Bulletin*, Department of Public Health, Victoria, Australia, No. 11, July–September, 1927, pp. 338–341. (Abstract by R. E. Tarbett.)

The article concerns itself with the viability of the newly hatched fly under adverse conditions. The newly hatched fly is able to work its way out of earth or other matter in which the pupa is buried, through the inflation and deflation of a frontal sac attached to the head between the eyes.

Experiments showed that house flies (*Musca domestica*), on emerging from the pupæ, were able to work their way through a covering of 6 to 7 inches of garden soil and a double layer of 2-millimeter mesh mosquito netting. Passage through the netting was made by inserting the sac within the mesh and then inflating. With the expanding of the wings, in the final development after exposure to the air, the capacity for inflating the frontal sac is lost.

In the experiments, pupæ were buried in 7 inches of sandy garden bed and at a depth of 6 inches in a pasteboard box. Temperature and rainfall were noted during the 18 days of the experiment. In the box experiment, an escape of 38 per cent was noted throughout a period of 16 days, and in the garden experiment 12 per cent during 18 days. The temperature during the 18 days varied from a maximum of 69° to a minimum of 47°.

A number of the flies after emergence from the soil were placed in a bottle without food or moisture, and notwithstanding a temperature of 40° on two of the nights they lived for four days.

The author suggests that the food in the digestive tract of the larvæ may pass on through the pupal period to the fly to "sustain it in the vicissitudes through which it may pass till it feeds."

Studies on the Bionomics of North American Anophelines. Winter Activities of Anophelines in Coastal North Carolina. Marshall C. Balfour. *American Journal of Hygiene*, vol. 8, No. 1, January, 1928, pp. 68–76. (Abstract by A. L. Dopmeyer.)

An account is given of observations made in the coastal area of northeastern North Carolina on the activity of anophelines, between November 1, 1926, and April 30, 1927, together with graphs, tables, and a summary as to the conclusions reached.

The studies are believed to be of interest because they represent more severe winter conditions than were met with when similar studies were made in Georgia, Alabama, and Louisiana.

In Chart I there are plotted against time by months, the following: (1) Adults caught per man-hour; (2) larvæ per 10 square meters; (3) temperature (mean maximum, air; mean, water; and mean minimum, air); (4) inches of rainfall. In Chart II there are plotted against time by months; (1) Adults caught per man-hour; (2) per cent fourth-stage larvæ and pupæ; (3) per cent third-stage larvæ; (4) per cent second-stage larvæ; (5) per cent first-stage larvæ.

Table No. 1 shows anopheline captures and larval identifications according to species, by months; Table No. 2 shows anopheline captures according to resting place; Table No. 3 shows breeding places classified according to type; and Table No. 4 shows breeding places classified according to water surface.

Twenty-first Biennial Report of the North Carolina State Board of Health, July 1, 1924–June 30, 1926. Bureau of Sanitary Engineering and Inspection. Pp. 62–82. (Abstract by J. K. Hoskins.)

The objectives, activities, and accomplishments of the sanitary engineering bureau of the North Carolina State Board of Health are very interestingly presented in this article, illustrated with numerous graphs and charts.

The work of the bureau consists of the following: (1) Sanitary inspection, (2) sanitary engineering, (3) milk sanitation, and (4) shellfish sanitation. The activities of each of these divisions are described and the results obtained are clearly depicted by means of graphs. Particular attention has been paid to the enforcement of the State sanitary privy law. Of a total rural population of 2,389,100 in 1925, 1,149,000, or over 48 per cent, were served by the privy law and public sewerage facilities. Of 184,313 surface privies eliminated since 1919, 66 per cent were replaced by improved types, 7 per cent were supplanted by construction of new sewerage systems, and 27 per cent by extensions to existing sewerage systems. Of the improved types installed, 81.9 per cent were earth pits, 11.8 per cent were septic privies, 4.9 per cent were of box and can system, 1 per cent were concrete vaults, and 0.4 per cent were chemical privies.

The 238 public water supplies, serving 28.37 per cent of the total State population, are under the supervision of the bureau. Of this number, 73 are filtered, 27 are unfiltered surface water supplies, and 138 are unfiltered ground water supplies, serving 573,000, 67,000, and 178,000 persons, respectively. Of the 73 filtered supplies, 38 are under trained operation and laboratory control and serve over 87 per cent of the total population using filtered water.

Improved milk sanitation is reflected in the extent of adoption of the standard milk ordinance. In the total of the 61 cities in the State, each having a population of 2,500 or over in 1920, 31, with a combined population of 401,000, equivalent to 65 per cent of the total State urban population, have enacted this legislation. Milk sanitation ratings of 10 cities, where records for 1924 and 1926 were available, showed an improvement in the efficiency of milk control by the enforcement of the standard milk ordinance, of 18.8 per cent. The average daily milk sales in eight of these cities in which figures were available during this period, increased 8 per cent.

Work in shellfish sanitation has included sanitary surveys of the growing areas, bacteriological examinations of shellfish, and inspection and improvement of shucking houses, all of which has resulted in reestablished public confidence in the safety of these food products.

"Prior to the state-wide activities in sanitation, particularly the enforcement of the sanitary privy law, begun in 1919, the urban rates [typhoid] were 50 per cent greater than the rural rates, and in 1925 the urban rates were only 60 per cent of the rural rates. This changed ratio is almost entirely the result of improved sanitation."

The Washington Suburban Sanitary District. Robert B. Morse. Proceedings of the 32nd Annual Convention of the American Society for Municipal Improvements. Pp. 181–191. (Abstract by J. L. Robertson.)

The Maryland suburbs of Washington lie in two counties. They comprise a large number of small municipalities, several special taxing districts, and numerous incorporated villages. The several water and sewerage systems, in original design, planned only for immediate needs, were inadequate as the demand on the systems increased. Realizing that development of this suburban district could be accomplished only through the installation of adequate water and sewerage systems, and that these must necessarily be under a single administrative body before an effective remedy could be had, action on the part of public-spirited citizens resulted in the report of two investigating committees and the legislative act establishing the Washington Suburban Sanitary District.

A commission of three members administers the affairs of the district. The county commissioners of each county appoint one member, upon recommendation of the State board of health, and the Governor appoints a third, all for four-year terms. The commission has the usual powers with respect to construction and operation of systems, and has power to purchase or condemn all municipal and private systems. Its bond issues must be approved by the public-service commission and its charges and rates are subject to review, upon appeal. Bonds for construction work up to 12 per cent of the assessable basis, may be issued without referendum.

There are two fundamental features of the legislation, one that relieves the towns of their powers and duties with respect to water supply and sewerage, and one that gives the commission the right to raise funds and proceed with all work without referendum.

It was realized that total costs of construction would be far greater than in an ordinary city of equivalent population, on account of the great expanse of territory. In order to distribute the great total cost and maintain equitable costs in proportion with benefits received, it was determined to meet the fixed charges on bonds through a small addition to the tax rate and a front-foot benefit charge on properties abutting on the water and sewer lines, and to cover maintenance and operating expenses on both water and sewer lines by water rates. While it was deemed essential that the rate structure adhere closely to correct theoretical principles, local conditions influenced the relative amounts of the charges.

Here much discussion is given to the front-foot benefit charges, particularly as to construction costs, property classification, assessments for improvements, etc. Also there are given the difficulties experienced and adjustments made by the commission.

Water and sewer house-connections are built to the property line; charges for connections are uniform.

The method employed by the commission to secure payment for construction and operation of the district's water and sewer systems results in a very small annual expense to the property not accessible to them, a larger one to undeveloped land along water and sewer lines, and a still greater one to developed lots receiving service.

Additional interesting notations are made concerning details of the commission's engineering practices.

A Cyanide Citrate Pour Plate Medium for Direct Determination of the Colon-Aerogenes Content of Water and Sewage. Ralph E. Noble. *Journal American Water Works Association*, vol. 19, No. 2, February, 1928, pp. 182–192. (Abstract by J. B. Harrington.)

The cyanide citrate pour plate medium which has been developed for the direct determination of colon-aerogenes is compared briefly with the present standard method as follows: (1) From 42 to 48 hours are required for the cyanide citrate determination as compared with 3 or 4 days' minimum time required for the present standard method; (2) the index by the cyanide citrate method represents more nearly the actual density of the organisms than does the present method; (3) the new method not only enables the colon-aerogenes group to be counted directly, but also indicates the fecal and aerogenes groups reasonably accurately, thereby eliminating the time-consuming Voges-Proskauer reactions; (4) the *B. coli* index by the new plate method is considered dependable. It is superior to that obtained by the lactose broth method and eliminates the difficulties involved in mathematical interpretation. The growth-inhibiting properties of the new medium are believed to be negligible at this time; (5) only the usual standard laboratory equipment is necessary in making the test.

Certain analytical and theoretical data are given for the direct determination of the colon-aerogenes organisms by the cyanide citrate pour method; also tables setting forth the concentration of ingredients.

The colon-aerogenes colonies usually appear on the plates in marked contrast to any of the other forms which may occur. The fecal types appear as small black or dark red disks or as triangular forms, diameter 0.5 mm. The grain types are usually pink, black (blue by reflected light), colorless, or black-sided disks, diameters 0.5 to 4.0 mm.

Comparative tests by the examination of a large number of samples have shown that the *B. coli* index was equal to or exceeded the tube method in 76.7 per cent of the samples and was less than the tube method in 23.3 per cent of the samples.

The cyanide citrate method, although in the experimental stage, is believed capable of being improved to such an extent that it may be of great value in the determination of the colon-aerogenes index of water, sewage, and even of milk.

The Water Resources of Rhode Island. Report of the commission appointed to investigate the sources of water supply for cities and towns, to the General Assembly at the January session, 1928. 126 pages. (Abstract by J. K. Hoskins.)

The report discusses the water resources of the State from the standpoint of the geologist, the chemist, and the engineer. The section on "Geology, Climate and Run-off," by Charles Wilson Brown, reviews the geological formations, the climatic factors, including temperature, precipitation and evaporation, and the run-off, which averages from 50 to 60 per cent of the rainfall.

The quality of the water supplies is ably discussed by Stephen DeM. Gage, under three general classes; namely, surface supplies without purification, used by 33.9 per cent of the entire State population; filtered surface supplies, used by 62.3 per cent, and ground-water supplies, used by 3.8 per cent of the total population. The physical and chemical characteristics and bacterial content of the individual public supplies are given in tabular form. Data concerning disinfection of certain of the public supplies are presented. The sanitary quality of 1,797 rural wells, as disclosed by examination, showed that 52 per cent were safe for domestic use, 23 per cent were doubtful, and 25 per cent were unsafe.

The engineering features such as populations supplied, drainage areas, rivers and streams, water supply developments, etc., are summarized by George H. Leland. Many detailed statistics are presented in the form of tables, including the physical characteristics of each of the public water supplies of the State.

Iron and Manganese Removal at Wausau, Wisconsin. Emil Flatter. *American City*, vol. 38, No. 3, March, 1928, pp. 125–126. (Abstract by C. R. Cox.)

This is a description of a 3–4.5 m. g. iron and manganese removal plant, costing $125,000. Well water of poor physical character is being effectively treated by aeration, coagulation and sedimentation, and filtration. Final chlorination is not needed. The aerator consists of shallow wooden racks, holding 5-inch layers of coke and 2-inch layers of manganese dioxide ore, which are arranged in vertical tiers. The aerated water is dosed with 7.4 g. p. g. alum and 3.5 g. p. g. lime before discharge through a baffled mixing chamber into a 45 by 45 by 16 foot Dorr clarifier, and then into three sedimentation basins, each 36 by 45 by 14 feet in size. Six rapid sand filters are fitted with porous concrete slab underdrains capable of passing 150 g. p. m. per square foot. Slabs are bolted to concrete stringers and have joints cemented. Slabs were made of ¾ to 1 inch gravel. A gravel layer of this size is used over slabs to depth of 6½ inches, then of ⅜ to ⅝ inch size to depth of 3 inches, and then of $\frac{3}{16}$ to ⅜ inch size to depth of 3 inches. Fine sand to depth of 28 inches is placed upon gravel. Complete control and recording apparatus is provided. From 2½ to 3 per cent wash water is used, which is somewhat high because considerable fine floc reaches the filters.

Oil Well Pollution Necessitates Auxiliary Water Supply. C. K. Mathews. *Engineering News-Record*, vol. 100, No. 9, March 1, 1928, pp. 358–360. (Abstract by W. J. Downer.)

Munroe, La., obtained its water supply from the Ouachita River until it became grossly polluted by oil-well wastes a hundred miles distant in another State. The situation was remedied by using the old supply during high dilutions and storing an auxiliary supply in an impounding reservoir for periods of high salt concentrations.

A 6 m. g. d. capacity rapid sand filter, clear well, and elevated tank are being constructed. The old coagulating basin is being remodeled to serve as an aerator for primary alum treatment for taste, odor, and color reduction.

The Treatment of the Water Supply of the City of Columbus, Ohio. Charles Hoover. Proceedings of the American Society of Civil Engineers, vol. 54, No. 2, February, 1928, pp. 471-484. (Abstract by H. M. Freeburn.)

The Columbus water supply is taken from the Scioto River, in which, during a three-day period, turbidity has varied from 22 p. p. m. to 2,250 p. p. m., with a drop of total hardness from 285 p. p. m. to 64 p. p. m. *B. coli* content has at times risen to 100,000 per 100 cubic centimeters.

The river water is pumped to a receiving compartment and divided into two equal parts. One part, without treatment, flows to baffled mixing tanks, while the entire quantities of lime, soda ash, and alum solution are added to the other part, which is then mixed by rotating paddles for 10 minutes. This overtreated portion of water with floc already formed joins other portion of untreated water and the two are passed through baffled mixing tanks having an hour's retention period. Water then flows to six settling basins, two of which must be cleaned every three or four weeks, and others about once or twice a year. Carbon dioxide gas is applied to clear softened water before it passes to filters to neutralize any excess lime, to convert normal carbonate to bicarbonate form, and to prevent after-reactions or deposits in filters or distributing system.

Advantages of lime treatment are as follows: (1) Water safe bacteriologically when sufficient quantity is added to produce caustic alkalinity; (2) increased efficiency of sedimentation; (3) water low in turbidity, color. and organic matter; (4) freedom from objectional gases; (5) lower cost of filtration.

Methods of handling lime, manufacturing alum, and of producing carbon dioxide gas are described. Tabulations show results of operation and quantities and cost of chemicals used.

Making producer gas from coke and burning it under the boilers is perhaps the most economical method of producing carbon dioxide gas. It is possible to produce gas containing 17 to 18 per cent of CO_2, thus requiring an air compressor of only one-fourth the capacity required if coke were burned in open burner.

DEATHS DURING WEEK ENDED MAY 5, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended May 5, 1928, and corresponding week of 1927. (From the Weekly Health Index, May 9, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended May 5, 1928	Corresponding week, 1927
Policies in force	70, 830, 030	67, 576, 686
Number of death claims	14, 992	14, 043
Death claims per 1,000 policies in force, annual rate	11. 1	10. 8

Deaths from all causes in certain large cities of the United States during the week ended May 5, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, May 9, 1928, issued by the Bureau of the Census, Department of Commerce)

North Dakota	47

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 99 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,275,000. The estimated population of the 93 cities reporting deaths is more than 30,590,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended April 28, 1928, and April 30, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
42 States	1,305	1,529	
99 cities	773	1,015	843
Measles:			
40 States	17,843	14,735	
99 cities	7,688	3,799	
Poliomyelitis:			
42 States	19	20	
Scarlet fever:			
42 States	3,846	4,536	
99 cities	1,583	2,006	1,271
Smallpox:			
42 States	976	734	
99 cities	152	122	109
Typhoid fever:			
42 States	142	275	
99 cities	26	49	44
Deaths reported			
Influenza and pneumonia:			
93 cities	1,343	926	
Smallpox:			
93 cities	0	0	

City reports for week ended April 28, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during non-epidemic years

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population, July 1, 1926, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported
			Cases, estimated expectancy	Cases reported	Cases reported	Deaths reported

[1] Typhus fever: 1 case at Miami, Fla., and 1 case at Tampa, Fla.
[2] Rabies (in man): 1 death at Dallas, Tex.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended April 28, 1928, compared with those for a like period ended April 30, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1927 and 1928, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,050,000 in 1927 and 31,657,000 in 1928. The 95 cities reporting deaths had nearly 30,370,000 estimated population in 1927 and nearly 30,961,000 in 1928. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, March 25 to April 28, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

THE FAR EAST

Report for the week ended April 14, 1928.—The following report for the week ended April 14, 1928, was transmitted by the eastern bureau of the health section of the secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

Aden Protectorate.—Aden.
India.—Bassein, Bombay, Rangoon.

India.—Bassein, Calcutta, Madras, Negapatam, Rangoon, Tuticorin.
French India.—Pondicherry.
Siam.—Bangkok.
French Indo-China.—Saigon.

SMALLPOX

Egypt.—Alexandria, Suez.
India.—Bombay, Calcutta, Madras, Moulmein. Nagapatam, Rangoon.
French India.—Pondicherry.
Straits Settlements.—Singapore.
Dutch East Indies.—Belawan-Deli, Banjermasin.
China —Canton, Shanghai, Hong Kong.
Japan.- Osaka, Shimonoseki.
Kwantung —Dairen.
South Manchuria.—Changchun.

Returns for the week ended April 14 were not received from Samarinda, Dutch East Indies; Basra, Iraq; or Vladivostok, Union of Soviet Socialist Republics.

CANADA

Provinces—Communicable diseases—Two weeks ended April 21, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from seven provinces of Canada for the two weeks ended April 21, 1928, as follows:

WEEK ENDED APRIL 14, 1928

	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Influenza	14			3				17
Smallpox				6		2	4	12
Typhoid fever	1		14	5		5	4	29

WEEK ENDED APRIL 21, 1928

	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever				1		3		4
Influenza	15					75		90
Smallpox				18		23	2	43
Typhoid fever		1	16	4	2			23

Quebec—Communicable diseases—Week ended April 28, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended April 28, 1928, as follows:

Disease	Cases	Disease	Cases
Chicken pox	54	Scarlet fever	103
Diphtheria	45	Smallpox	19
German measles	19	Tuberculosis	39
Influenza	3	Typhoid fever	26
Measles	261	Whooping cough	28

CHINA

Hong Kong—Plague—May 4, 1928.—A case of plague was reported in Hong Kong, China, May 4, 1928.

ECUADOR

Duran—Guayaquil—Plague—March, 1928.—During the month of March, 1928, 10 cases of plague with 1 death were reported in Ecuador, of which 4 cases with 1 death occurred at Duran (Eloy Alfaro) and 6 cases at Guayaquil.

Plague-infected rats.—During the same period, of 20,846 rats taken, 21 rats were found plague infected.

Guayaquil—Smallpox.—During the period under report, 24 cases of smallpox with 1 death were reported at Guayaquil.

Esmeraldas Province—Epidemic bacillary dysentery—April 7, 1928.—Bacillary dysentery in epidemic form was reported present in Esmeraldas Province, Ecuador, April 7, 1928.

GERMANY

In German cities the birth, death, and infant mortality rates were all lower in February, 1928, than they were in February, 1927. The following table gives vital statistics for 49 German cities for January and February, 1928, and 46 cities for February, 1927:

	1928—49 cities		February, 1927—46 cities
	January	February	
Marriages	9,657	11,929	10,213
Live births, total	20,401	19,530	18,718
Live births, illegitimate	2,936	2,849	2,875
Deaths, total	18,125	15,800	18,595
Deaths under 1 year of age	2,044	1,888	1,998
Deaths from—			
Tuberculosis	1,529	1,408	1,425
Diseases of respiratory organs	2,443	1,959	3,144
Heart diseases	2,349	2,066	2,195
Rates per 1,000 population:			
Marriages	6.5	8.5	7.8
Births, total	13.7	14.0	14.3
Births, illegitimate	2.0	2.0	2.2
Deaths—			
Total	12.1	11.3	14.2
Tuberculosis	1.02	1.01	1.09
Respiratory organs	1.64	1.40	2.40
Heart disease	1.57	1.48	1.68
Infant mortality	100	97	107

ITALY

Communicable diseases—January 16–29, 1928.—During the two-week period, January 16 to 29, 1928, communicable diseases were reported in the Kingdom of Italy as follows:

Disease	Jan. 16-22, 1928		Jan. 23-29, 1928	
	Cases	Communes affected	Cases	Communes affected
Anthrax	20	16	10	10
Cerebrospinal meningitis	3	3	9	9
Chicken pox	313	122	410	121
Diphtheria	498	287	458	264
Dysentery	4	3	6	4
Lethargic encephalitis	6	6	8	8
Measles	2,380	310	2,896	341
Poliomyelitis	5	5	6	6
Scarlet fever	351	168	353	164
Typhoid fever	368	230	448	229

JAPAN

Tokyo, city and district—Dysentery—January 29–March 24, 1928.—During the eight weeks January 29 to March 24, 1928, dysentery was reported in Tokyo city and district (prefecture) as follows: Tokyo city, cases 186, deaths 62; prefecture, cases 197, deaths 102. Population of city, 1,995,567; population of prefecture, 2,489,577.

SALVADOR

Mortality for January and February, 1928.—During the months of January and February, 1928, the total numbers of deaths occurring in the Republic of Salvador were 3,111 and 2,638, respectively. Population in 1927, 1,688,000.

San Salvador.—During the same period deaths from communicable diseases were reported in the city of San Salvador as follows:

Disease	January, 1928	February, 1928
Gastroenteritis	20	22
Tuberculosis	19	18
Typhoid fever	1	1

Population, 1927: 88,000.

UNION OF SOUTH AFRICA

Orange Free State.—Plague—During the week ended March 24, 1928, two fatal cases of plague, in natives, were reported in the Orange Free State, in Bultfontein area, on a farm.

Plague infection in veldt rodents.—Area of spread.—During the past few months plague infection in veldt rodents is stated to have spread

in the Union of South Africa from the Coega River Valley, in the Uitenhage district, where its existence has been recognized for some years past, eastward as far as the Sundays River Valley, southward throughout the entire Port Elizabeth district and the immediate vicinity of the town of Port Elizabeth, and westward to a point 5 miles east of Thornhill railway station. No definitely plague-infected rodents have been found, but numerous decomposed carcasses of rodents, evidently dead from plague, have been found within 5 miles of the town.

Typhus fever.—During the week ended March 24, 1928, typhus fever was reported in the Cape Province in five districts; in Natal, at Pietermaritzburg municipality, with three cases in Europeans, and present on an estate at Braemar, Umzinto district.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst. Surg. Gen. R. C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM

SEX DIFFERENCES IN THE INCIDENCE OF CERTAIN DISEASES AT DIFFERENT AGES[1]

Hagerstown Morbidity Studies No. IX[2]

By Edgar Sydenstricker, *Statistician, United States Public Health Service*

The present paper is, in a sense, a continuation of the reports on "The Illness Rate among Males and Females," and on "The Incidence of Various Diseases According to Age," previously published, since its purpose is to present the results of the Hagerstown morbidity study bearing on the incidence of certain diseases as manifested in illness among males and females at different age periods.

Since the scope and method of the study in which the basic data were obtained have been set forth at considerable length in the first paper of this series, and since especial reference may be made to the two papers mentioned above, it will not be necessary to repeat what already has been said. The comparability of the records for males and females is so essential, however, to whatever observations may be made in this paper that the question ought to be given rather careful consideration before presenting the data and in discussing the results of the study.

As was stated in the first paper of this series, the record of illness in our study was furnished by an adult member—usually the mother of the family—of each household visited. Might not this fact mean that a more complete record of illnesses, particularly the minor

[1] From the Office of Statistical Investigations, U. S. Public Health Service.

VIII. The Incidence of Various Diseases According to Age. Pub. Health Rep. vol. 43, No. 19. Reprint No. 1227.

ailments or those conditions which were manifested by subjective symptoms, was obtained for these informants than for other members of the household?

It is at once apparent that this condition could have no appreciable effect upon the illness rate among younger persons (up to 20 years of age); but the possibility of its effect upon comparative rates for certain diseases among adult males and females is undoubtedly great. This applies with especial force, of course, to diseases the occurrence of which is manifested in subjective symptoms only and the diagnosis of which is differentiated thereby. The records of diseases and conditions which manifest themselves in objective ways obviously are not so liable to this error. But undoubtedly the tendency on the part of the informant to report illnesses incident upon herself more completely than illnesses in others must nearly always be regarded as a weakness in the data whenever the method of collecting them does not eliminate it.

This weakness in the present study is difficult to eradicate, and we can only do so partially by two methods. One is to limit comparison of rates for males and females to those diseases which do manifest themselves in objective rather than subjective ways. The other is to select from our population groups of persons of opposite sex whose records were not subject to this incomparability. Both of these methods were followed, with the results that the illness data are reported (1) as recorded for persons of different sex-age groups for infectious diseases, diseases and conditions of the eye, ear, skin and kidneys and annexa, and external causes; (2) as recorded for other diseases and conditions for persons of different sexes and ages *under 20 years of age;* and (3) as recorded in a selected group of adults. The selection of the latter group was made in such a way as to eliminate as far as possible the effect of the condition already referred to, that many women reported their own illnesses and ailments whereas relatively few men did, as follows: We used the records of those families in which more than one adult female and at least one adult male were continuously resident. Since the original record contained a notation as to the identity of the informant on each case of illness, it was possible to compare the incidence of illness among those for whom other informants gave the information. In order to render as comparable as possible the two sets of records, only persons of adult age were included. A comparison of three groups was possible: (1) Women reporting upon themselves; (2) women reported upon by other women in the same households; and (3) men in the same households who were reported upon, usually by their wives.

The size of the experience in each sex and age group, upon which the results presented in this communication are based, was as follows:

Number of white males and females observed for the incidence of disease in Hagerstown, Md., December 1, 1921–March 31, 1924, expressed in terms of "years of life observed" and classified by age

Age, in years	Number of years of life observed	
	Males	Females
All ages [1]	8,001	8,516
0–4	942	835
5–9	1,093	1,012
10–14	846	867
15–19	677	712
20–24	523	613
25–29	545	691
30–34	581	654
35–44	1,038	1,133
45–54	822	854
55–64	428	472
65 and over	346	464

[1] Includes population of unknown age.

The data as recorded for those diseases which we considered fairly suitable for sex comparisons in any age period are given in Table 1. The rates on an annual basis are given in Table 2.

TABLE 1.—*Number of cases of certain diseases and conditions among males and females in a canvassed group of white persons of Hagerstown, Md., December 1, 1921–March 31, 1924*

Disease or condition	Sex	Number of cases							
		All ages [1]	0–4	5–9	10–14	15–24	25–44	45–64	65+
Epidemic, endemic and infectious diseases (1–42, except 11 and 31).	Males	740	336	326	87	13	15	8	2

[1] Includes rash, hives, and sores on body.

The incidence of infectious diseases was found to be higher among boys than among girls, which is in line with general morbidity and mortality experience. In every age period after 10 years, however, the female rate is higher than the male rate, an indication which is not so generally observed and regarding which not a great deal of data have been published. The number of cases for most of the diseases included under this general title is too small to warrant comparisons according to age.[3] For measles, whooping cough, and chicken pox the number of cases is perhaps sufficiently large to record for different age groups, and is given in Tables 3, 4, and 5, and plotted in Figure 1. The male rate for measles, which disease occurred in epidemic form during the period of study, was under that of females; the reverse was true for chicken pox and whooping cough.

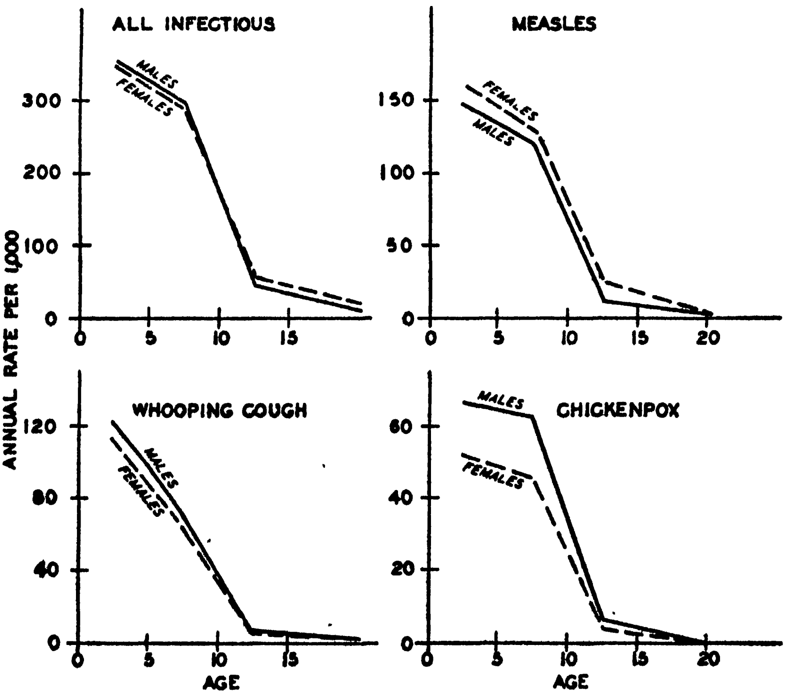

FIG. 1.—Incidence of infectious diseases manifested in illness among boys and girls in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

[3] See Tables 1 and 2 in Hagerstown Morbidity Studies No. I for number of cases and rates by diseases for males and females of all ages.

TABLE 3.—*Incidence of measles among males and females, by age, in a canvassed group of white persons of Hagerstown, Md., December 1, 1921–March 31, 1924*

65+				

With reference to eye diseases and conditions, as shown in Figure 2 some differences between the sexes are apparent which may not be really significant on account of the small numbers involved. The excess in the male rate under 10 years of age was confined to a slightly higher incidence of pink eye and conjunctivitis, which possibly reflects the generally higher prevalence of infections among boys than among girls. The excess in the female rate in the older adult ages was due to "other eye trouble," which might have resulted from a failure on the part of informants to report similar conditions for males.

The sex-age curves for ear diseases and conditions are generally similar, as Figure 3 shows. The somewhat higher rate among girls aged 5 to 9 was due to a greater prevalence of otitis media and

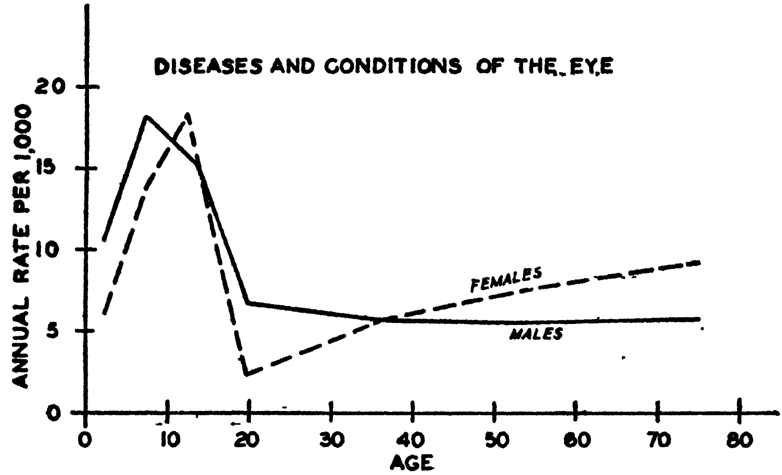

FIG. 2.—Incidence of diseases and conditions of the eye as manifested in illness among males and females of different ages in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

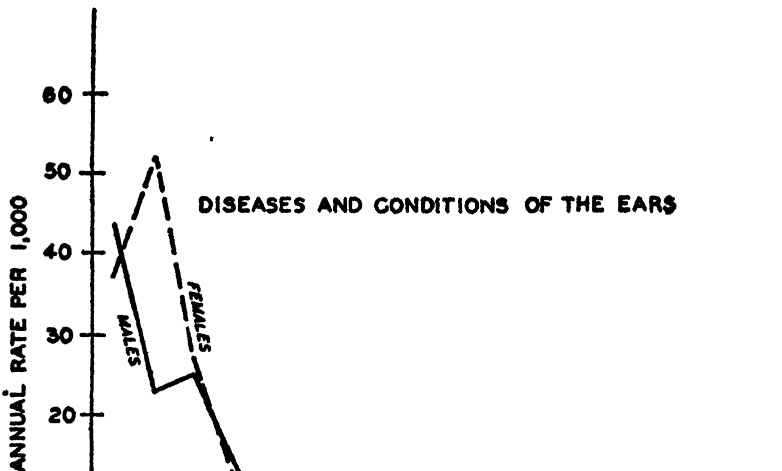

FIG. 3.—Incidence of diseases and conditions of the ear as manifested in illness among males and females of different ages in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

"earache," but the numbers are not large enough to justify any generalization.

The excess in the male rate for skin diseases and conditions under 20 years of age, as shown in Figure 4, occurs in spite of the fact that scabies and pediculosis were somewhat more prevalent among girls than among boys, as shown by Collins' data for the Hagerstown school children (*1*). This indication is again in accordance with the tendency for boys to be affected by infectious conditions to a greater extent than girls. In other age groups the age curves for this group of diseases is generally similar.

Keeping in mind the fact that practically all disabilities resulting from external causes were accidents, the rate for males is higher than that for females in every age period and is relatively highest in the

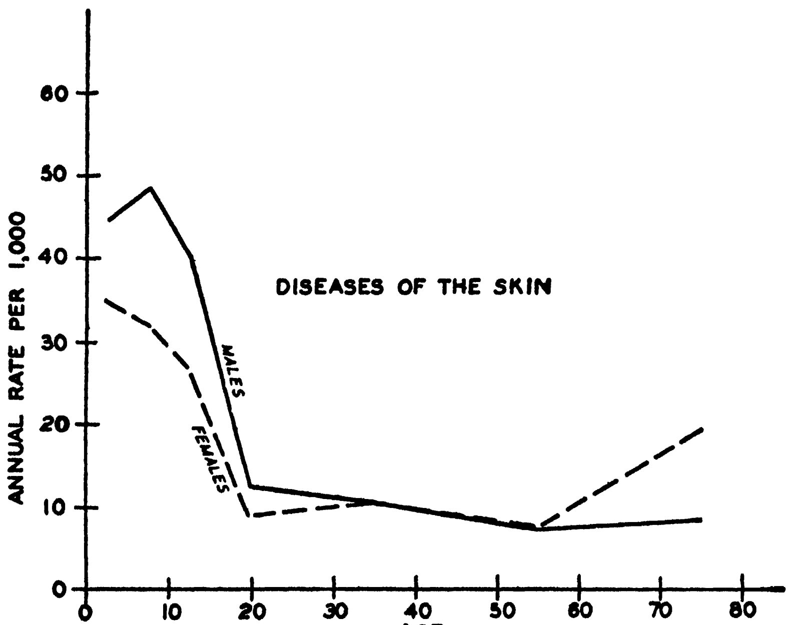

FIG. 4.—Incidence of diseases of the skin as manifested in illness among males and females of different ages in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

young adult (15 to 44 years) ages. (See Table 2 and fig. 5.) The accidents included are both industrial and nonindustrial; and this greater excess in the adult male rate at these ages may be safely ascribed to the greater frequency of accidents occurring directly or indirectly in connection with work. The proverbial greater adventuresomeness of boys is borne out by these accident statistics, and is exhibited in greatest degree in the age period 5 to 9 years. Between the ages of 9 and 15 the sex difference is diminished considerably, the accident rate for boys decreasing and the rate for girls increasing.

The size of the excess in the female rate over the male rate for nonvenereal diseases of the genito-urinary system from the beginning of

adolescence until old age was somewhat surprising and led us to doubt the comparability of the record for the two sexes. In all probability the records are not comparable from the viewpoint of completeness, but that there is a considerable excess in the female rate can not be doubted, for this group of diseases and conditions includes dysmenorrhea and kindred conditions that are peculiar to women. Brundage (*2*) reports for the (Boston) Edison Co. an annual rate of only 9 disabilities of one day or longer per 1,000 males for nonvenereal genito-urinary diseases as against 314 per 1,000 females of which 306 were due to dysmenorrhea and kindred conditions. These are ex-

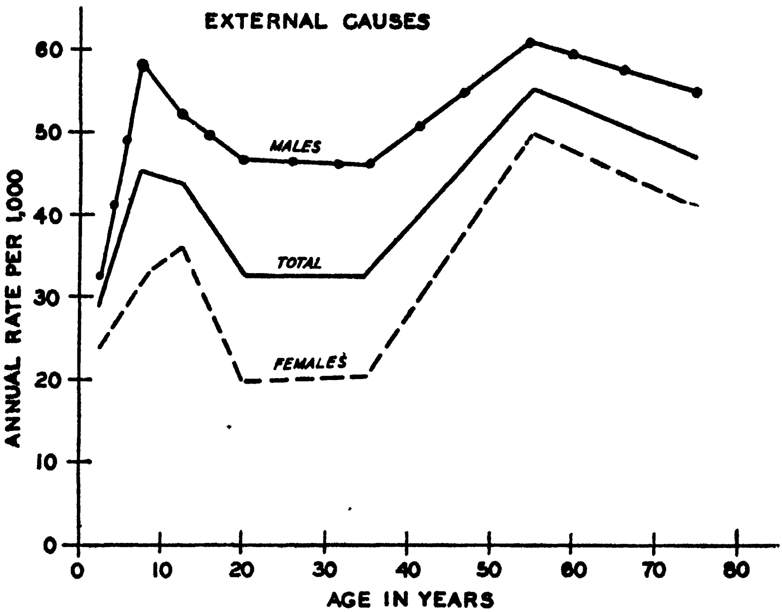

FIG. 5.—Incidence of disabilities from external causes among males and females of different ages in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

clusive of puerperal diseases and conditions which are shown separately in Figure 6. (For data and rates see Hagerstown Morbidity Studies, No. VIII.)

Sex differences in the incidence of respiratory, nervous, digestive, and circulatory diseases probably are accurately indicated by our records for persons under 20 years of age for the reason that those individuals were reported upon by some other person, usually the mother. (See Tables 7, 10, 11, and 13.) Therefore we have plotted the age specific rates for the four disease groups in Figure 7. The indications are not without interest. In general, young boys were affected to a greater extent than young girls by all of these diseases, but in adolescence precisely the opposite is true. Respiratory diseases and conditions were more frequent among boys in the age

periods 0 to 4 and 5 to 9, and among girls in the ages 10 to 24. Although both sexes under 5 years of age were affected about equally by nervous diseases and disorders, in the succeeding quinquennial period the male rate was higher, followed by a definite excess in the female rate in the age period 10 to 24. The excess in the male rates for digestive diseases and disorders, and circulatory conditions and diseases was confined to the age period 0 to 4 years; in the age period 5 to 9 years and in adolescence the female rates for both disease groups were definitely in excess of the male rates, especially for circulatory diseases and conditions. The number of cases is hardly large enough

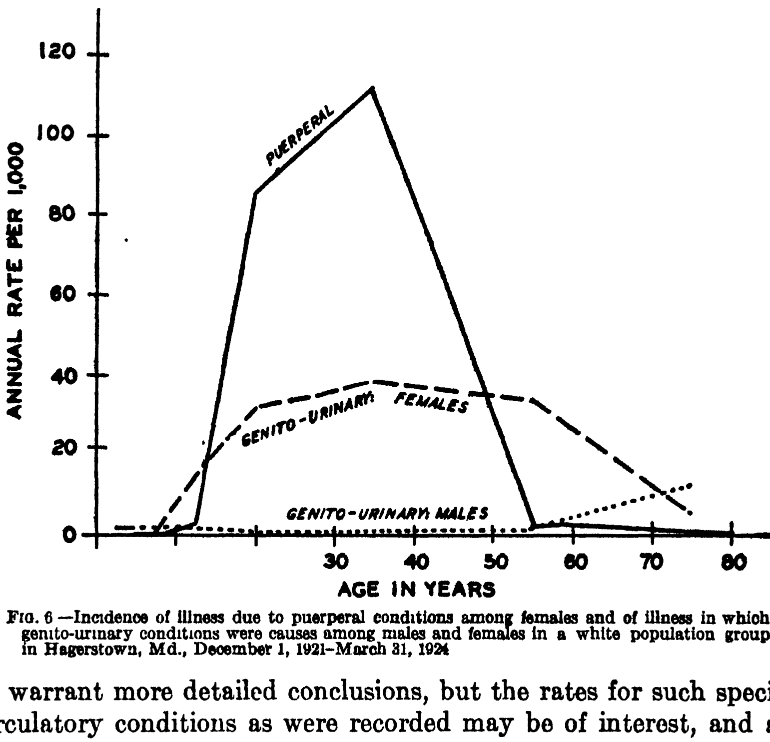

FIG. 6.—Incidence of illness due to puerperal conditions among females and of illness in which genito-urinary conditions were causes among males and females in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

to warrant more detailed conclusions, but the rates for such specific circulatory conditions as were recorded may be of interest, and are presented in Table 6.

TABLE 6.—*Incidence of specific circulatory diseases and disorders among males and females under 25 years of age in a white population group of Hagerstown, Md., December 1, 1921–March 31, 1924*

Condition	Sex	Annual rate per 1,000 for age periods			
		0-4	5-9	10-14	15-24
Heart disease	Males		0.92	4.73	5.00
	Females		3.95	15.00	9.06

	Females	7.18	8.90	8.07	2.26
Hemorrhage [1]	Males	1.06	3.66		
	Females			1.15	.75

[1] Including "nose bleeding."

TABLE 7.—*Incidence of respiratory attacks among males and females, by age, in a canvassed group of white persons of Hagerstown, Md., December 1, 1921,–March 31, 1924*

Age	Annual rate per 1,000		Number of cases [1]		Age	Annual rate per 1,000		Number of cases [1]	
	Males	Females	Males	Females		Males	Females	Males	Females
All ages	602	723	4,815	6,157	25-29	407	586	222	405
0-4	974	861	917	719	30-34	437	724	254	474
5-9	949	919	1,037	930	35-44	427	734	443	832
10-14	733	838	620	726	45-54	470	701	386	599
15-19	469	579	318	412	55-64	452	688	193	325
20-24	384	539	201	330	65+	477	666	165	309

[1] Including cases among 59 males and 96 females whose ages were not known accurately enough for classification.

Adenitis thus accounted for the excess in the male rate under 5 years of age, whereas the female rate for every condition save one was higher in the later ages.

We may now turn to some comparisons of disease incidence in adult males and females that are more difficult, because of the possibility that the records are more complete for females than for males.

The respiratory illness rate as recorded by us was higher among females in every age period except under 10 years. As already noted, the excess of the male rate in children was greatest under 5 years, diminished in the second quinquennial period, and in the third the reverse appeared. The excess of the female rate then continues throughout the remainder of the life span. These results are in conformity with those found by Surgeon J. G. Townsend and the writer (*3*) in the experience of families of medical officers of the Army, Navy, and Public Health Service, for persons up to 25 years of age, but are in contradiction to those found for persons 25 years of age and over. The ratios of the female respiratory rates to the male rates at different ages in the medical officers' families were as follows:

Ratio of respiratory attack rate among females to that among males in families of medical officers of Army, Navy, and Public Health Service, 1924

Age	Ratio $\frac{\text{female}}{\text{male}}$	Age	Ratio $\frac{\text{female}}{\text{male}}$
0-4	0.94	25-34	0.80
5-9	.92	35-44	.92
10-14	1.09	45-54	.83
15-24	1.23	55+	.96

Now, the attacks in the medical officers' families were reported by the medical officers themselves, and the medical officers constituted practically all of the male population 35 years of age and over; in the middle and later adult ages, therefore, the males reported upon

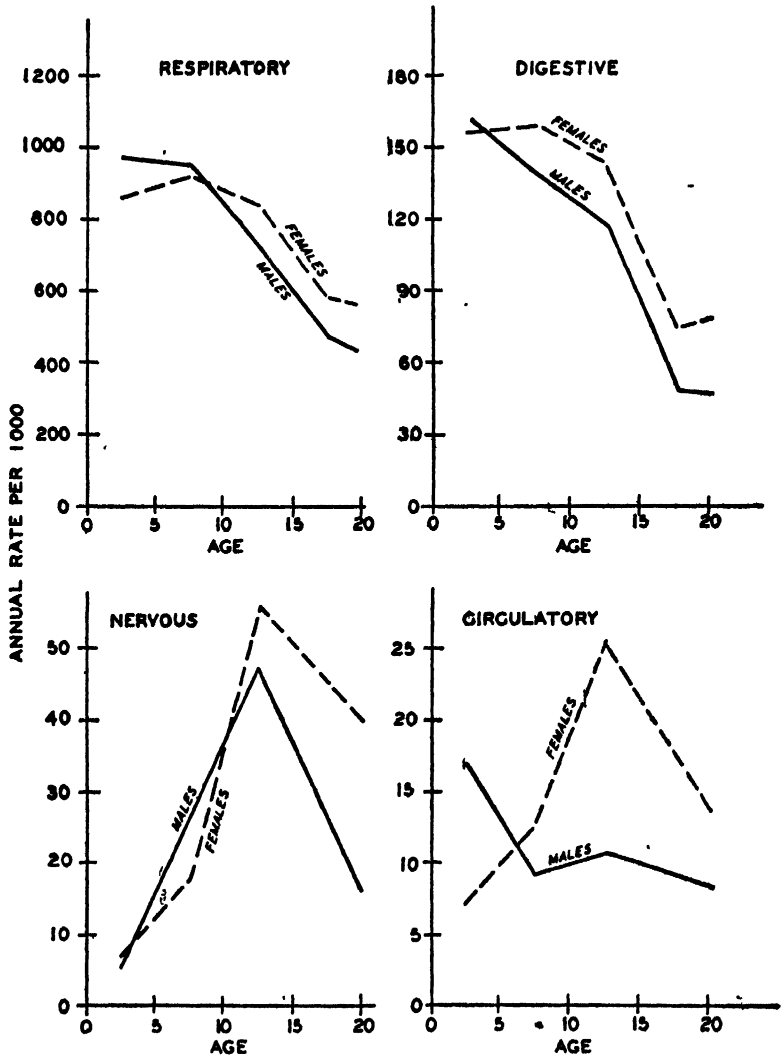

FIG. 7.—Incidence of respiratory, digestive, nervous, and circulatory diseases and conditions as manifested in illness among boys and girls in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

themselves, which is in contrast to the situation in Hagerstown, where, in the middle and later adult ages, the females reported upon themselves. The difference in the results of these two studies would seem to be due, therefore, chiefly to differences in the source of

information.[4] The possibility that one result may be nearer the truth than the other, however, ought to be considered, and the matter need not rest here; for, using the records for Hagerstown households where both adult males and adult females were *reported upon*, we find that the ratio of the adult female respiratory rate to the adult male was 1.2 to 1. For the entire adult population observed, this ratio was 1.5 to 1. So that for the kind of respiratory attacks that were recorded in the Hagerstown study the influence of the source of information upon its accuracy in this particular respect does not seem to account for all of the higher rate for females. Furthermore, this Hagerstown result is corroborated by all the indus-

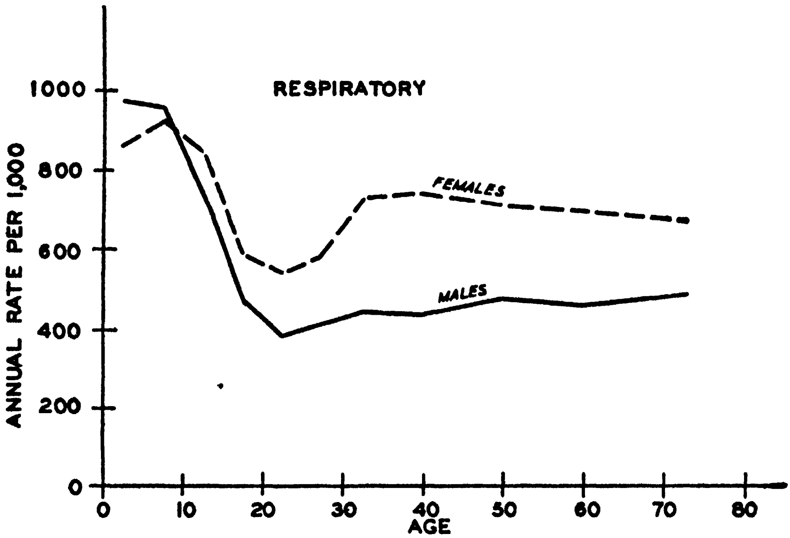

FIG 8—Incidence of respiratory diseases as manifested in illness among males and females in a white population group in Hagerstown, Md, December 1, 1921–March 31, 1924

trial morbidity experience bearing upon this point that we have collected For example, Brundage (*2*) has reported the (Boston) Edison Co.'s 10 years' experience of illness resulting in at least one day of disability, which gives a ratio of the adult female respiratory rate to the adult male rate of 1.70 to 1. Similarly, four years' records (*4*) of more serious illnesses (eight days or more of disability) among a large group of industrial employees has shown a sex ratio of 1.47 (females) to 1 (males) for respiratory diseases, exclusive of influenza, for which the ratio is 1.10 to 1.

[4] The data of the two studies are not comparable in some other respects Thus the annual respiratory attack rate in the medical officers' families was 2,009 per 1,000, as contrasted with only 657 in the Hagerstown group In the latter, only those attacks which manifested themselves in some degree of illness, as the word is ordinarily understood, were recorded, whereas in the former group it was the intention to secure records of all definite respiratory attacks regardless of the degree of sickness involved. Again, in the medical officers' families practically every attack was reported by a physician, whereas in the Hagerstown group only a small proportion of respiratory attacks of a minor nature were attended by physicians.

TABLE 8.—*Number of cases of diseases of the kidneys and annexa among males and females in a canvassed group of white persons of Hagerstown, Md., December 1, 1921—March 31, 1924*

Disease or condition	Sex	Number of cases							
		All ages [1]	0-4	5-9	10-14	15-24	25-44	45-64	65+
Diseases of kidney and annexa (128-134)	Males	77	3	7	4	3	14	22	23
	Females	160	13	5	7	8	36	56	31
Nephritis, acute and chronic (128, 129)	Males	31	1	1	1	1	6	9	12
	Females	52			2	5	2	23	19
Kidney trouble (unqualified) (131)	Males	24	1	3	3	2	5	5	5
	Females	67	13	4	5	3	22	14	5
Calculi of the urinary passages (132)	Males	7					2	4	1
	Females	7					1	4	2
Cystitis (133)	Males	5					1	1	3
	Females	18					8	9	4
Bladder trouble (133)	Males	10	1	3				3	2
	Females	14		1			6	6	1

[1] Includes cases among 1 male and 4 females whose ages were not known accurately enough for classification.

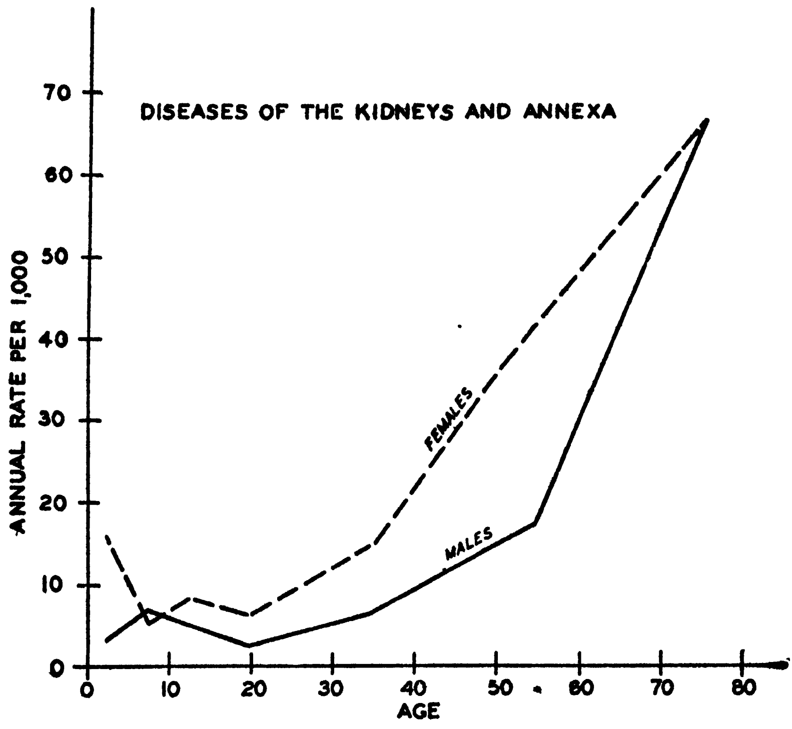

FIG. 9.—Incidence of diseases of the kidneys and annexa as manifested in illness among males and females in a white population group in Hagerstown, Md., December 1, 1921-March 31, 1924

The rates as given in Table 7 and as plotted in Figure 8 do, we believe, represent a real sex difference in the incidence of respiratory diseases according to age in a general population group.

The excess of the female rate for kidney diseases at almost every age, as shown in Tables 8 and 9 and Figure 9, is contrary to mor-

tality experience. Whether or not the illnesses from these causes were more completely reported for females than for males, it is difficult to say; the number of cases was too small, in the selected group already referred to, to yield any indication on this point. Keeping in mind that the experience for the entire population is not large, the consistency of the excess in the female rate is not without possible significance. The detailed rates of diseases in this group are given as a matter of record, but we are not in a position to comment upon the apparent sex differences at the present time.

TABLE 9.—*Incidence of diseases of the kidneys and annexa among males and females in a canvassed group of white persons of Hagerstown, Md., December 1, 1921–March 31, 1924*

Disease or condition	Sex	Annual rate per 1,000							
		All ages	0–4	5–9	10–14	15–24	25–44	45–64	65+
Diseases of kidney and annexa (128–134)	Males	9.6	3.2	6.4	4.7	2.5	6.5	17.6	66.5
	Females	18.8	15.6	4.9	8.1	6.0	14.5	42.2	66.8
Nephritis, acute and chronic (128, 129)	Males	3.9	1.1	.9	1.2	.8	2.8	7.2	34.7
	Females	6.1			2.3	3.8	.8	17.3	40.9
Kidney trouble (unqualified) (131)	Males	3.0	1.1	2.8	3.6	1.7	2.3	4.0	14.5
	Females	7.9	15.6	4.0	5.8	2.3	8.9	10.6	10.8
Calculi of the urinary passages (132)	Males	.9					.9	3.2	2.9
	Females	.8					.4	3.0	4.3
Cystitis (133)	Males	.6					.5	.8	8.7
	Females	2.1					1.2	6.8	8.6
Bladder trouble (133)	Males	1.3	1.1	2.8				2.4	5.8
	Females	1.6		1.0			2.4	4.5	2.2

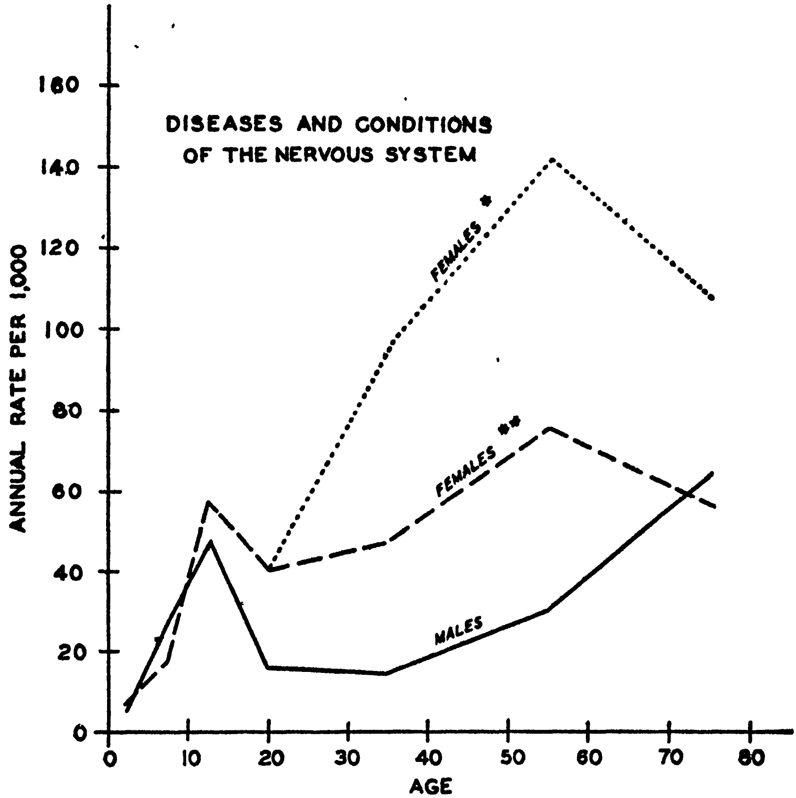
The female rate for diseases and conditions of the nervous system, as it was recorded (Table 10), is higher than the male rate in every age group after 10 years. Since we have included under this heading all headaches that presumably were not symptoms of some other condition noted, and since most of the manifestations of these diseases and conditions are subjective in character, some of the excess of the female rate in adult ages might easily have been due to the tendency for women informants to have reported more completely their own ailments than those of their husbands.

TABLE 10.—*Incidence of diseases of the nervous system, by age, among males and females in a canvassed group of white persons of Hagerstown, Md., December 1, 1921–March 31, 1924*

Age	Annual rate per 1,000		Number of cases [1]		Age	Annual rate per 1,000		Number of cases [1]	
	Males	Females	Males	Females		Males	Females	Males	Females
All ages	23.3	72.3	186	616	15–24	15.8	40.0	19	53
0–4	5.3	7.2	5	6	25–44	14.3	96.1	31	238
5–9	26.5	17.8	29	18	45–64	29.6	141.7	37	188
10–14	47.3	56.5	40	49	65+	63.6	107.7	22	50

[1] Including cases among 3 males and 14 females whose ages were not known accurately enough for classification.

As a matter of fact, in those households where a comparison could be made of the rates for the two sexes when both were reported upon by others, the ratio of the adult female to the adult male rate for nervous diseases was only 2.58 to 1, as contrasted with 4.94 to 1 for the entire adult population studied. In plotting the sex-age curves in Figure 10 for illnesses in which nervous diseases or conditions were involved, a rough correction has been attempted for this factor by reducing the recorded rate by 48 per cent. The female rate is still



* Rate as recorded.
** Rate as estimated from the incidence among families reported upon by informants other than themselves.

FIG. 10.—Incidence of diseases and conditions of the nervous system as manifested in illness among males and females in a white population group in Hagerstown, Md., December 1, 1921–March 31, 1924

in excess of the male rate from the ages 10 to 65, and this indication is corroborated by our industrial morbidity experience. For example, the (Boston) Edison Co.'s (*2*) 10 years' record shows a ratio of female rate to male rate of 4.1 to 1 for nervous disabilities of one day or longer. The four years' record of illness causing disability of eight days or longer in a large group of industrial workers showed a ratio of 2.4 to 1 (*4*).

Similarly, our record of digestive diseases (Table 11) shows a considerable excess in the adult female rate over the adult male rate in all age periods, but in the group of males and females reported upon by others in the same household this excess persists to the extent of a ratio of 1.8 to 1, which is not so greatly below that for the entire adult population, which was 2.1 to 1. Brundage (*2*) data for the (Boston) Edison Co. give a ratio of 2 to 1, while the records of more serious digestive illnesses (*4*) give a ratio of 1.8 to 1. The excess of the adult female illness rate from digestive causes seems, therefore, to be about 80 to 100 per cent above the male rate. For some of the specific diseases and conditions the rates (all ages) are shown in Table 12.

TABLE 11.—*Incidence of diseases of the digestive system among males and females, by age, in a canvassed group of white persons of Hagerstown, Md., December 1, 1921–March 31, 1924*

Age	Annual rate per 1,000		Number of cases [1]		Age	Annual rate per 1,000		Number of cases [1]	
	Males	Females	Males	Females		Males	Females	Males	Females
All ages	83.6	119.3	669	1,016	15–24	48.3	74.0	58	98
					25–44	42.0	96.9	91	240
0–4	161.4	155.7	152	130	45–64	68.1	147.8	85	196
5–9	139.1	158.2	152	160	65+	83.8	114.2	29	53
10–14	117.0	143.0	99	124					

[1] Includes cases among 3 males and 15 females whose ages were not known accurately enough for classification.

TABLE 12.—*Incidence of certain digestive diseases and conditions among males and females as recorded in a white population group of Hagerstown, Md., December 1, 1921–March 31, 1924*

Disease or condition	Annual rate per 1,000		Disease or condition	Annual rate per 1,000	
	Males	Females		Males	Females
"Indigestion" and "upset stomach"	40.1	49.1	Hernia	2.3	1.1
"Stomach trouble" and nausea	7.4	9.2	Biliary calculi	1.4	7.2
Diarrhea	12.0	14.4	Cholecystitis	.4	3.4
Appendicitis	3.3	8.6	Jaundice	2.3	3.2
			"Biliousness"	7.3	13.4

The Hagerstown record of the illness rate from diseases and conditions of the circulatory system among adults is at variance with industrial experience. As indicated in Table 13, the adult female rate is higher than the male rate in all age periods except "65 years and over," whereas the Edison Co.'s (*2*) experience of disabilities of one day or longer due to these causes shows that the female rate was only 82 per cent of the male rate and the industrial employees' record of disabilities lasting eight days or longer shows that the female rate was 92 per cent of the male, all of these wage earners being under 65 years of age. The wage earners were all

actively employed, however, and it is possible that a higher prevalence of circulatory diseases may characterize the nonwage-earning women than men. Upon this point we have no adequate data as yet.

TABLE 13.—*Incidence of diseases of the circulatory system among males and females, by age, in a canvassed group of white persons of Hagerstown, Md., December 1, 1921–March 31, 1924*

Age	Annual rate per 1,000		Number of cases [1]		Age	Annual rate per 1,000		Number of cases [1]	
	Males	Females	Males	Females		Males	Females	Males	Females
All ages	18 4	29 4	147	250	15–24	8 3	13 6	10	18
					25–44	11.6	19.4	25	48
0–4	17.0	7.2	16	6	45–64	26.4	60.3	33	80
5–9	9 2	12 9	10	13	65+	124 2	112.0	43	52
10–14	10 6	25.4	9	22					

[1] Includes cases among 1 male and 11 females whose ages were not known accurately enough for classification.

SUMMARY

To summarize our findings on differences in the incidence of various diseases as manifested in illness between males and females:

In general, the incidence of most diseases is higher among boys than among girls under the age of 5, and for some diseases the excess of the male rate persists in the age group 5 to 9 years. In the adolescent ages, however, the opposite is true, the principal exceptions being diseases of the ears and eyes. In the adult ages, the Hagerstown records show a higher female rate for all diseases for which comparisons are warranted. The only definite exception to the excess in the female rate in ages 10 years and over is the incidence of disabilities from external causes, nearly all of which were accidents.

ACKNOWLEDGMENTS

The continuous field observations upon which the foregoing report is based were made by the following assistants: F. Ruth Phillips, Mrs. Mary King Phillips, Louise Simmons, Mrs. Clara Bell Ledford, Clarice Buhrman, and Mrs. Alcesta Owen, under the immediate supervision of Passed Asst. Surg. R. B. Norment, jr., Acting Asst. Surg. A. S. Gray, and, later, Surg. C. V. Akin.

In the analysis of the data I am especially indebted to Miss Phillips and to Associate Statistician S. D. Collins and Assistant Statistician Dorothy G. Wiehl, and other members of the statistical staff, as well as to several officers of the Public Health Service for constant advice on medical points.

STATISTICS OF ADMISSIONS TO HOSPITALS FOR THE INSANE

The United States Public Health Service is making an attempt to secure and publish regularly current monthly data relative to admissions to hospitals for the care and treatment of insane persons in the United States. For this purpose monthly reports are being sought from institutions in each State which care for this class of patients, and it is believed that, with the cooperation of these hospitals, the information published will be of considerable value not only to all persons interested in mental hygiene, but to health authorities generally. For the present time it will be possible to secure and classify the data by sex and psychoses only. It is desired, of course, to make these statistics as complete as possible, and therefore the cooperation of all institutions for insane patients is most earnestly desired.

On page 1288 of this issue of Public Health Reports there are published the reports that have been received of first admissions to hospitals for the insane for the month of January, 1928. The tabulation includes 2,103 first admissions classified by psychoses and by sex of patient. These reports were received from 83 institutions, located in 30 States, the District of Columbia, and the Territory of Hawaii. Reports from other institutions are expected, and data for later months will be published as soon as compiled.

COURT DECISION RELATING TO PUBLIC HEALTH

Lighting and ventilation provision in city housing code upheld.—(Oregon Supreme Court; Daniels *v.* City of Portland et al., 265 P. 790; decided March 27, 1928.) The housing code of the city of Portland, which code came into existence in 1919, contained a provision reading as follows:

SEC. 123. No room in a dwelling erected prior to the passage of this code shall hereafter be occupied for living purposes unless it shall have a window of an area of not less than 8 square feet opening directly upon the street, or upon a rear yard not less than 10 feet deep, or above the roof of an adjoining building, or upon a court or side-yard not less than 25 feet square in area, open to the sky without roof or skylight, unless such room is located on the top floor and is adequately lighted and ventilated by a skylight opening directly to the outer air.

A hotel building, constructed in 1907 under a permit granted by the city pursuant to the building code provisions then in force, had certain rooms, designed as sleeping and housekeeping rooms, with windows opening only upon a light well or court. The said light well or court was covered at the top with a sloping canopy, constructed partly of translucent glass and partly of wood or other supporting material, and the only opening in the canopy was a small ventilator. The plaintiff, the owner of the hotel, alleged that the chief health inspector of the city, under threat of immediate arrest, illegally ordered and directed him to remove the skylight over the court, or immediately to cease using or renting for sleeping purposes rooms having windows opening on the court. In a suit to enjoin the city from enforcing the above-quoted provision of the housing code the plaintiff contended that the said provision was unconstitutional, and that the ordinance was arbitrary and not a proper exercise of the police power vested in the city. The supreme court stated that the right of regulation, under the police power, was not limited by the fact that the value of an investment would be lessened, and that, as the record tended to show an unhealthful condition in the matter of ventilation, it became the plaintiff's duty, upon complaint to the proper authorities, to abate the condition in some feasible and efficient manner. Regarding the plaintiff's assertion that the ordinance was retrospective, the court said that the building permit granted by the city for the construction of the hotel did not "affect the right of the police power of the city of Portland to adopt and apply to it regulative measures looking to the public health." The trial court's decree, dismissing the complaint, was affirmed.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Preliminary Report of the Investigation of the Pollution of the Mississippi River in the Vicinity of Minneapolis and St. Paul. H. R. Crohurst. Unpublished report made under supervision of U. S. Public Health Service in cooperation with the States of Minnesota and Wisconsin and the cities of Minneapolis and St. Paul. 86 pages. (Abstract by H. R. Crohurst.)

The basic data collected during a study of the pollution of the upper Mississippi River, between Minneapolis and Winona, Minn., in connection with a joint investigation by the Public Health Service, the States of Minnesota and Wisconsin and the cities of Minneapolis and St. Paul, during the period June, 1926–August, 1927, has been made available, in mimeograph form, for the use of the cooperating agencies, to assist in the solution of the sewage-disposal problem existing in that portion of the Mississippi River.

The report contains summarized results, as monthly averages of the chemical and bacteriological examinations and the hydrometric data. Population estimates, estimates of sewered population, population equivalent to industrial wastes, and other pertinent data are presented.

The disposal of the sewage of the Twin Cities, by dilution, is complicated by a dam located below Minneapolis, behind which there is a considerable deposition of sewage solids from the city sewage as a result of decreased velocity in the river. The problem of the disposal of the sewage from the remainder of the metropolitan area will be still further complicated by the construction of a second dam, in the near future, which will form a second pool immediately below the present one and will decrease the velocity in the river through St. Paul and South St. Paul.

Indications are that the sewage load in the river will increase so that objectionable conditions through the Twin Cities and as far down stream as Hastings will be of frequent occurrence in the future. The formation of the second pool will intensify the present objectionable conditions.

Studies of methods of sewage disposal are being conducted by the Metropolitan Drainage Commission, created by the last legislature and by the Minnesota State Department of Health. It was primarily to make available the basic data relative to conditions existing in the river, for the use of these State organizations, that the preliminary report was prepared.

Milwaukee Metropolitan Sewerage District Problem. T. Chalkley Hatton. Proceedings of Ninth Texas Water Works Short School, January 24–29, 1927. pp. 297–300. (Abstract by H. E. Hargis.)

The city of Milwaukee has a population of approximately 560,000 and an area of 34 square miles, and surrounding it are 13 separate municipalities of a combined population of 80,000. The city of Milwaukee obtains its water from an intake 70 feet below the lake surface and 6,500 feet from shore. The average daily flow of sewage is about 65,000,000 gallons, and all the water that was used for drinking purposes had *B. coli* present, necessitating chlorination.

In 1913 a statute was passed creating a sewage commission for the city of Milwaukee, but this commission had no power outside the city limits. In 1921, however, a statute was passed creating a metropolitan sewerage commission, and giving it authority to build a sewage-treatment plant outside the city of Milwaukee, and to collect all the sewage from the outlying towns and dispose of it here. The cost of operation was to be assessed against the municipalities in proportion to the amount of sewage each contributed.

An activated sludge plant was installed with a maximum capacity of 128,000,000 gallons. By November 1, 1925, the plant was in operation and satisfactorily treating about 70,000,000 gallons a day. At present it is costing about $11 per

million gallons to treat the sewage, not including interest, sinking fund, or depreciation.

The Public Works of the Ruhr Sanitary District. Karl Imhoff. Pamphlet in German, June, 1927. 8 pages. (Abstract by A. L. Dopmeyer.)

The Ruhr River Sanitary District was established by a Prussian law on June 5, 1913. Its sole purpose is to prevent pollution of the Ruhr River and its tributaries. The total contributing population is about 1,300,000. Industrial wastes are contributed by coal mines, iron and steel works, tanneries, textile works, and cellulose and paper works. According to the law one-third of the cost of carrying on the work of the district is paid by the water works, since they are considered as receiving the greatest benefit.

Most of the construction work has been carried on in the last four years, during which time total expenditures for the years were as follows: 1923, $472,000; 1924, $710,000; 1925, $1,150,000; 1926, $1,970,000; 1927, estimated, $2,140,000.

The works consist of sewage-disposal units, sewerage systems, and pumping plants. To date 36 disposed units, 56.5 miles of collecting sewer, and five pumping plants have been built.

For three towns located near the mouth of the Ruhr, a collecting sewer 6.8 miles long was constructed, which carries this sewage to the main stream—the River Rhine.

In other sections where it was impossible to divert sewage directly to the Rhine, various types of disposal plants have been installed. The methods of treatment used at various places are listed in this article and there are a number of photographic views.

Separate sludge digestion is used in one town of 16,000 and in another of 12,500. A sludge digestion tank, in which the sludge is heated, is used at one place. The sludge digestion tank was installed as an addition to the original Emscher tank. Heat is obtained by burning the gas from the treatment plant. Chlorination of sewage is used only to a limited extent. An activated sludge plant is used at Essen-Rellinghausen, population 45,000. There are very few treatment plants for handling industrial wastes alone, and it has been the general rule to mix the wastes with domestic sewage and treat the mixture.

Stream Pollution in Wisconsin. Wis. State Bd. Health, 1927. pp. XVIII+328. Experiment Station Record, U. S. Dept. of Agriculture, vol. 58, No. 6. April, 1928, p. 585.

"This is a joint report of the Conservation Commission and the State Board of Health of Wisconsin concerning their activities in the control of stream pollution from July 1, 1925, to December 31, 1926.

"The data reported indicate that the discharge of industrial waste into certain streams is the only practical method of ultimate disposal in many cases and constitutes a necessary and proper use of the stream, provided the dilution is so great that there is no menace to public health nor material interference with the natural aquatic life of the stream.

"Nearly all wastes cause reduction of the dissolved oxygen of the stream, and industrial wastes generally have a greater oxygen demand than domestic sewage. Biological oxidation is more rapid during warm weather than during cold weather, so that the oxygen demand of the waste is greater, although the actual amount of oxygen available is less, since warm water retains less oxygen in solution. When the dissolved oxygen of a stream is depleted, green plants and other grasses of aerobic life die and anaerobic organisms such as worms and lower animal life prevail. A stream tends to purify itself by natural processes and will ultimately return practically to normal if the concentration of the wastes is not too great.

"The results of an experimental investigation concerning the efficiency and practicability of chemical treatment in removing substances from pea-cannery wastes that cause local nuisances and objectionable stream pollution showed that by careful operation and the application of about 3.25 pounds of ferrous sulphate and 7.25 pounds of lime per 1,000 gallons of waste, the oxygen demand can be reduced approximately 75 per cent. If the sludge is allowed to accumulate in the tank, the oxygen demand reduction averages only 34 per cent, because the precipitated organic matter goes partially into solution and is carried through the tank. Aeration of the tank effluent will effect a further reduction in the oxygen demand, approximately 50 per cent being indicated by laboratory tests. The chemical treatment will materially reduce stream pollution and prevent local nuisances created by pea-cannery wastes.

"Studies in the treatment of sulphite waste liquor from pulp and paper mills to reduce its oxygen demand in the control of stream pollution showed that ponding and aeration of the waste will effect a very material reduction in its oxygen demand. Mechanical aeration will also reduce the oxygen demand.

"Data from stream pollution surveys are also included."

The Effect of the Activation of Sewage Sludge on Pathogenic Organisms. H. Bruns and F. Sierp. Abstract by M. E. Delafield in *Bulletin of Hygiene*, vol. 2, No. 2, November, 1927, pp. 904–905. (Abstract by R. E. Tarbett.)

Experiments with activated sludge method of sewage treatment were carried on to determine the reduction in pathogenic organisms where definite numbers of such organisms were added to the raw sewage. Sewage containing 450,000 typhoid organisms per cubic centimeter was found to undergo a reduction of 96 per cent after 12 hours' treatment, the greatest effect being secured in the first 6 hours. The clear effluent was practically free from the organisms, such as remained being in the sludge.

Similar reductions were obtained in the case of paratyphoid, bacillary dysentery, and cholera. Anthrax spores were found to have a much greater resistance.

It is suggested that the bacterial destruction is due to the bacteriophagic power of the sewage plankton.

Sanitary Supervision of Tourist Camps and Recreation Places. Lewis S. Finch. *The American City*, vol. 36, No. 5, May, 1926, pp. 661–664. (Abstract by D. W. Evans.)

For the last four years an inspection of all tourist camps has been made by the water and sewage department of the State board of health of Indiana. Water supplies are sampled, methods of disposal of garbage and sewage are investigated, and unsatisfactory conditions noted. The final report of the survey, with recommendations, is sent to the owner and to the local health officer. It is the duty of the latter to require that all recommendations be carried out, otherwise the camp is declared a health nuisance and may be ordered closed. During 1926, of the 233 camps operating, 104 were approved. The regulations dealing with these subjects are noted in the article and include headings on supervision, drainage, water supply, sewage, garbage or waste disposal, and enforcement of the rules.

The second topic gives a general statement with regard to sanitation of resorts, and it is brought out that the "Lake Order" of 1926 will indirectly improve conditions at the resorts by requiring treatment of sewage before discharge into a lake. The third topic briefly states the regulations dealing with swimming pools as tentatively adopted by the conference of State sanitary engineers.

The efficient operation of any of these recreational features depends mainly upon close supervision by an experienced operator, while the responsibility of seeing that sanitary conditions are maintained rests entirely with the local health officer.

Zeolitic Water Softening. Ray Riley. Proceedings of Ninth Texas Water Works Short School, January, 1927, pp. 139–143. (Abstract by H. D. Cashmore.)

A semitechnical discussion of the zeolitic method of softening water and its applications.

The terms "hard" and "soft" are only relative terms and are dependent on the individual using them and the section of the country from which he comes. Hard water is not only an annoyance but an expense. Precipitation of the hardening constituents costs more in soap than the amount of soap required for cleaning purposes; and when this item is eliminated, the saving will in many cases pay for the cost of softening.

The two methods of water softening, namely, the lime-soda process and the zeolite process, are compared as to use, cost and results obtained. The lime-soda method is more suitable where large amounts of water are used; but when small supplies are to be treated, the zeolite method is less expensive. This method has found application to textile industries, power plants, laundries, hotels, and houses. Following are some of the advantages: (1) Complete removal of hardness with no "after reactions"; (2) unaffected by fluctuations in hardness; (3) occupies a small space and simple in operation.

A great deal of variation exists in the zeolites upon the market to-day in reference to operation. There are two general classes of zeolites: (1) Those of natural origin—from clay, from glauconite or greensand; and (2) synthetic—precipitated, gel type. A detailed discussion is given regarding the production and use of these two groups.

The real operation or procedure of softening water by this method is a chemical engineering problem. There are many details which must be worked out and are included in this discussion.

Nitrites Formed in Water by Chlorination. C. E. Morgan. *Water Works*, vol. 67, No. 3, March, 1928, pp. 125–126. (Abstract by C. R. Cox.)

The water supply of Miami, Fla., is derived from wells drilled in limestone. The well water is colored and has a large organic content, especially albuminoid ammonia, but there are no nitrites present in the raw water. The water is coagulated and softened and filtered, but not chlorinated at all times. Following the hurricane, the filtered water was chlorinated. It was ascertained that apparently a large residual chlorine content existed at distant points in the distribution system. Investigation indicated that this was due to the reaction of nitrites with orthotolidine, the nitrites being formed by the oxidation of the albuminoid ammonia by the chlorine. The orthotolidine test is still available for determining chlorine, provided the test is made within 30 minutes after the chlorine is applied. The reaction of nitrites and orthotolidine is slow, requiring 20 minutes for maximum color to appear. False results were also secured when nitrites reacted with starch-iodide reagent.

The Value of Laboratory Tests in Water-Works Operation. A. E. Berry. *Contract Record and Engineering Review*, vol. 42, No. 11, March 14, 1928, pp. 291–294. (Abstract by R. E. Thompson.)

A general discussion, with particular reference to conditions in Ontario. Fifty of the 240 waterworks systems in operation in Ontario include filtration plants, and over 110 employ chlorination. Considerably over 75 per cent of all water used for domestic purposes is purified. The Department of Health maintains 8 laboratories, in addition to an experimental station, located at convenient points to serve the whole Province. Last year over 20,000 samples were analyzed, but, unfortunately, most of these were from a limited number of supplies. Fifty per cent of the supplies had less than 50 analyses made, and 40 per cent had none whatever. The expenditure for a plant laboratory may frequently be offset by the savings in cost of treatment accomplished thereby. Reports are not uncommon in which are recorded reductions in chemicals to the extent of 50 per cent and

amounting to several thousand dollars per year as a result of laboratory control. The importance of adequate plant records is stressed.

New Filtration Plant at Waukegan, Illinois, Designed on Duplex Plan. Anon. *Water Works*, vol. 67, No. 3, March, 1928, pp. 97–102. (Abstract by C. R. Cox.)

This article is a description of a modern rapid sand filtration plant, with many interesting features, designed to filter Lake Michigan water. The plant is designed as two independent units with suitable cross connections to permit any one portion of one unit to be operated with the other portions of the other unit. A specially designed raw water aerator is used, which operates on the injector principle, whereby air is drawn through numerous tubes as the water flows by the ends of the tubes. The air is carried with the water to the bottom of a tank, and then rises to the surface, thus causing agitation of the water, which mixes the coagulant added just prior to aeration. The aerated water is then discharged into covered coagulating basins of 3½-hour capacity, and then to 10 rapid sand filter beds. The filters are conventional except for the underdrains. A cast-iron header is located in the front wall of each filter, and 20 bronze underdrains project across the bottom of each filter from these headers. The tubes are embedded in the furrows of a ridge and furrow concrete bottom, with ⅛-inch holes drilled on the upper side of the tubes, which are flush with the bottom of the furrows. Clear wells are located under each row of 5 filter beds. Duplicate chlorination equipment, with two machines in each unit, is used to chlorinate the filtered water flowing to duplicate, secondary aerators of the same design as the primary aerator. The chlorinated and aerated water then enters duplicate covered storage reservoirs with a 12-hour detention period. Provisions have been made for split or double chlorination in case this is found to be desirable.

The Effect of Slightly Alkaline Tap Water Upon Spawn and Eggs of Trout and Perch. Edward S. Hopkins. *Journal American Water Works Association*, vol. 19, No. 3, March, 1928, p. 313. (Abstract by J. H. O'Neill.)

The impossibility of hatching or raising brook or rainbow trout at the Druid Hill Tank hatchery, supplied with water from the city supply of Baltimore, Md., led to a study of the cause of the high mortality among the fish.

Experiments were made with three types of water: (*a*) The Baltimore water. alkaline, and with high oxygen content and no free carbon dioxide; (*b*) water from Lewiston, containing free carbon dioxide and high oxygen content; (*c*) a spring water containing free carbon dioxide and low oxygen content.

It was found that trout and perch would not live in water (*a*) but would live and thrive in the other two waters. When artificially carbonated to a pH value of about 6 to 7, water (*a*) was not detrimental to fish life. These experiments indicated that free carbon dioxide, regardless of the oxygen concentration, is necessary in water for the sustenance of fish life.

Saving and Keeping Elevated Water Storage Tanks or Towers and Standpipes in Sanitary Condition. D. W. Pyle. Proceedings of Ninth Texas Water Works Short School, January, 1927, pp. 219–220. (Abstract by H. D. Cashmore.)

Many tanks are lost through laxity in the proper and timely care of the surfaces. The surfaces should be cleaned by an electric wire brush and the paint supplied by a compressed-air spray.

The installation of a clean-out valve has the following advantages: (1) Sediment can be flushed out without emptying tank or removing it from service; (2) many tanks have the riser main extending up into the tank some distance, making it impossible to flush by draining without a clean-out valve; (3) cleaning by means of a flush valve prevents the contamination due to other methods.

The bottom of standpipes should be fitted with 3-inch or 4-inch valve and covered with a coat of rock asphalt or tar higher on the opposite side. This permits efficient flushing by the pressure of the water alone.

DEATHS DURING WEEK ENDED MAY 12, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended May 12, 1928, and corresponding week of 1927. (From the Weekly Health Index, May 16, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended May 12, 1928	Corresponding week, 1927
Policies in force	71, 171, 763	67, 645, 777
Number of death claims	15, 891	12, 728
Death claims per 1,000 policies in force, annual rate	11. 7	9. 8

Deaths from all causes in certain large cities of the United States during the week ended May 12, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, May 16, 1928, issued by the Bureau of the Census, Department of Commerce)

ADMISSIONS TO HOSPITALS FOR THE INSANE, JANUARY, 1928

Reports for the month of January, 1928, showing new admissions to hospitals for the care and treatment of the insane have been received by the Public Health Service from 83 institutions located in 30 States, the District of Columbia, and the Territory of Hawaii. Sixteen of these institutions were corporate or private. These hospitals reported a total of 113,720 patients on January 31, 1928, including those on parole.

The following table shows the numbers of new admissions for the month of January, 1928, by psychoses.

First admissions to 83 hospitals for the insane, January, 1928

Psychoses	Male	Female	Total
Traumatic psychoses	7	0	7
Senile psychoses	114	85	199
Psychoses with cerebral arteriosclerosis	93	54	147
General paralysis	136	36	172
Psychoses with cerebral syphilis	29	27	56
Psychoses with Huntington's chorea	2	1	3
Psychoses with brain tumor	1	2	3
Psychoses with other brain or nervous disease	18	15	33
Alcoholic psychoses	64	10	74
Psychoses due to drugs and other exogenous toxins	8	6	14
Psychoses with pellagra	3	17	20
Psychoses with other somatic diseases	22	32	54
Manic-depressive psychoses	155	155	310
Involution melancholia	17	29	46
Dementia præcox (schizophrenia)	248	177	425
Paranoia and paranoid conditions	22	21	43
Epileptic psychoses	35	31	66
Psychoneuroses and neuroses	19	23	42
Psychoses with psychopathic personality	17	8	25
Psychoses with mental deficiency	51	35	86
Undiagnosed psychoses	140	44	184
Without psychosis	67	27	94
Total	1,268	835	2,103

Thirty-nine and seven-tenths per cent of the new admissions were females and 60.3 per cent were males, giving a ratio of 152 males per 100 females. The 83 institutions on January 31, 1928, had 59,973 male patients and 53,747 female patients, the ratio being 112 males per 100 females.

Undiagnosed psychoses constituted 8.7 per cent of the total admissions; dementia præcox, 20.2 per cent; manic-depressive psychoses, 14.7 per cent; senile psychoses, 9.5 per cent; general paralysis, 8.2 per cent; psychoses with cerebral arteriosclerosis, 7 per cent; and 4.5 per cent were recorded as without psychosis.

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 101 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,650,000. The estimated population of the 95 cities reporting deaths is more than 30,960,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended May 5, 1928, and May 7, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
42 States	1,276	1,062

City reports for week ended May 5, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during non-epidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended May 5, 1928, compared with those for a like period ended May 7, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1927 and 1928, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,050,000 in 1927 and 31,657,000 in 1928. The 95 cities reporting deaths had nearly 30,370,000 estimated population in 1927 and nearly 30,961,000 in 1928. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, April 1 to May 5, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

SMALLPOX ON VESSEL

Steamship "Yarmouth"—At Kingston, Jamaica, from Boston via ports—April 7, 1928.—During the week ended April 7, 1928, the steamship *Yarmouth* from Boston, via Miami, April 2, and Habana, April 4, 1928, arrived at Kingston, Jamaica, with a case of smallpox on board. The *Yarmouth* sailed from Kingston April 7, for New York, arriving April 12, 1928.

THE FAR EAST

Report for the week ended April 21, 1928.—The following report for the week ended April 21, 1928, was transmitted by the Eastern Bureau of the Health Section of the Secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Egypt—Suez
Aden Protectorate—Aden, Perim
India—Bassein, Bombay, Rangoon
Siam—Bangkok

CHOLERA

India—Bassein, Calcutta, Madras, Moulmein, Rangoon, Tuticorin
French India—Pondicherry
Siam—Bangkok
French Indo China—Saigon

SMALLPOX

India—Bombay, Calcutta, Madras, Moulmein, Rangoon, Tuticorin, Vizagapatam.
French India—Pondicherry
Straits Settlements—Singapore
China—Shanghai, Hong Kong
Japan—Osaka, Shimonoseki
Kwantung—Dairen
South Manchuria—Changchun
Manchuria—Mukden, Antung
Chosen—Fusan

Returns for the week ended April 21 were not received from Samarinda, Dutch East Indies, Basra, Iraq, nor Vladivostok, Union of Soviet Socialist Republics.

CANADA

Provinces—Communicable diseases—Week ended April 28, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from seven Provinces of Canada for the week ended April 28, 1928, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Influenza	10					11		30
Poliomyelitis				3				3
Smallpox				18		15	3	36
Typhoid fever	4	1	26	1	3	1	5	41

Quebec—Communicable diseases—Week ended May 5, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended May 5, 1928, as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	2	Scarlet fever	110
Chicken pox	25	Smallpox	33
Diphtheria	27	Tuberculosis	80
German measles	13	Typhoid fever	12
Influenza	9	Whooping cough	8
Measles	216		

CZECHOSLOVAKIA

Communicable diseases—March, 1928.—During the month of March, 1928, communicable diseases were reported in Czechoslovakia as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Cerebrospinal meningitis	17	12	Rabies	1	1
Diphtheria	908	67	Scarlet fever	1,145	47
Dysentery	10	3	Trachoma	248	
Malaria	10		Typhoid fever	535	43
Paratyphoid fever	5		Typhus fever	25	
Puerperal fever	79	28			

DENMARK

Communicable diseases—February, 1928.—During the month of February, 1928, communicable diseases were reported in the Kingdom of Denmark as follows:

Disease	Cases	Disease	Cases
Broncho-pneumonia	2,932	Paratyphoid fever	11
Cerebrospinal meningitis	3	Pneumonia	480
Chicken pox	60	Poliomyelitis	2
Diphtheria	680	Puerperal fever	14
Erysipelas	294	Scarlet fever	242
Influenza	4,934	Tetanus	5
Jaundice	192	Tuberculosis	209
Lethargic encephalitis	12	Typhoid fever	9
Measles	6,694	Whooping cough	1,767
Mumps	752		

Population of Denmark: 3,493,000.

FINLAND

Communicable diseases—February, 1928.—During the month of February, 1928, communicable diseases were reported in Finland as follows:

Disease	Cases	Disease	Cases
Diphtheria	80	Scarlet fever	199
Influenza	3,702	Smallpox	1
Paratyphoid fever	40	Typhoid fever	49
Poliomyelitis	1		

Population: 3,558,220.

Helsingfors.—During the period under report, cases of communicable diseases were reported in the city of Helsingfors as follows: Diphtheria, 6; influenza, 874; paratyphoid fever, 3; scarlet fever, 54. (Population, 215,829.)

ITALY

Communicable diseases—January 30–February 12, 1928.—During the period January 30 to February 12, 1928, communicable diseases were reported in the Kingdom of Italy as follows:

Disease	Jan. 30–Feb. 5, 1928		Feb. 6–12, 1928	
	Cases	Communes affected	Cases	Communes affected
Anthrax	16	16	19	18
Cerebrospinal meningitis	6	4	8	8
Chicken pox	312	121	426	126
Diphtheria	439	266	469	288
Dysentery	2	2	6	4
Lethargic encephalitis	4	4	6	6
Measles	2,791	336	2,859	324
Poliomyelitis	5	5	12	12
Scarlet fever	329	189	342	138
Smallpox	2	2	2	2
Typhoid fever	353	189	360	203

JAMAICA

Smallpox (Alastrim)—March 25–April 28, 1928.—During the period March 25 to April 28, 1928, 11 cases of smallpox (alastrim) were reported in the island of Jamaica, occurring in localities not included in the Kingston area.

Communicable diseases.—During the same period other communicable diseases were reported in the island as follows:

Disease	Cases		Disease	Cases	
	Kingston	Other localities		Kingston	Other localities
Cerebrospinal meningitis		1	Leprosy		1
Chicken pox	3	53	Puerperal fever		1
Dysentery	6	34	Tuberculosis	24	57
Erysipelas		1	Typhoid fever	28	87

Population: Kingston, 62,707; island, 926,000.

MALTA

Communicable diseases—March, 1928.—During the month of March, 1928, communicable diseases were reported in the island of Malta as follows:

Disease	Cases	Disease	Cases
Broncho-pneumonia	19	Puerperal fever	3
Cerebrospinal meningitis	1	Scarlet fever	6
Chicken pox	36	Trachoma	41
Diphtheria	4	Tuberculosis	28
Erysipelas	6	Typhoid fever	20
Influenza	28	Undulant (Malta) fever	48
Malaria	[1] 1	Whooping cough	6
Pneumonia	8		

[1] Contracted abroad.

Population, civil, 228,575.

Mortality from communicable diseases—March, 1928.—During the period under report mortality from communicable diseases was reported in the island of Malta as follows: Diphtheria, 1 death; tuberculosis, 13; typhoid fever, 3.

MEXICO

State of Jalisco—Smallpox—March and April, 1928.—An epidemic of smallpox in March and April, 1928, was reported from unofficial sources in the Los Altos region, State of Jalisco, Mexico. The disease is said to have been severe in Tepatitlan.

SYRIA

Beirut and the Lebanon—Smallpox—April 2-15, 1928—Summary.—During the period April 2 to 15, 1928, 8 new cases of smallpox were reported at Beirut, Syria, and 4 cases at other localities in the Lebanon. The total number of cases reported from January 26 to April 17, 1928, was for Beirut 106, and for other localities in the Lebanon 63 cases.

UNION OF SOUTH AFRICA

Orange Free State—Smallpox—Typhus fever.—During the week ended March 31, 1928, fresh outbreaks of smallpox and typhus fever were reported in the Orange Free State, occurring on farms in the Koffefontein and Ladysmith Districts, respectively.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

ASST SURG GEN. R. C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

PUBLIC HEALTH REPORTS

VOL. 43 JUNE 1, 1928 NO. 22

CURRENT WORLD PREVALENCE OF COMMUNICABLE DISEASES [1]

United States, April 8–May 5, 1928

The mortality from all causes in large cities continued high during the four weeks ended May 5 as compared with the corresponding weeks of last year; the average death rate in 66 large cities (annual basis) in these weeks was 15 per 1,000 population in the current year, 13.7 a year ago, and 14.2 in 1925. The average rate in the current year is the same as that for the preceding four weeks, and no tendency for the mortality to decline was indicated. The death rate for the week ended May 5 was 15.5, the highest so far reported for the cities this year. While the normal seasonal decline is somewhat overdue and the April mortality was higher than in the recent years not affected by marked respiratory epidemics, the general death rate in these cities for the first 18 weeks of 1928 (14.4) was about average; it was slightly higher than that for the corresponding period of 1927 (13.8), but the same as the rate in 1925. A comparison with 1926 is not made, since the mortality rate for the corresponding period of that year was abnormally high because of a respiratory epidemic.

Influenza and pneumonia.—Reported cases of influenza increased during April, and in the week ended May 5 there were 4,185 cases reported by 31 States, as compared with 3,300 in the preceding week. This increase occurred chiefly in Indiana, Wisconsin, Minnesota, North Dakota, Missouri, Arkansas, Texas, and New Mexico. The mortality from influenza and pneumonia in 95 cities was slightly lower for the two weeks ended April 21, the latest available, than for the preceding two weeks, when a maximum rate of 250 per 100,000 was reported, as shown in the accompanying table. The decline occurred in the average death rate for cities reporting in each of the geographic divisions except the West North Central and Mountain States. The mortality from influenza and pneumonia in these cities in the current year has exceeded that in 1927 in all sections except the South Atlantic and Pacific divisions, and the excess has been most marked in the East and West South Central and East North Central States.

[1] From the Office of Statistical Investigations, U. S. Public Health Service.

Average death rates per 100,000 (annual basis) from influenza and pneumonia in cities in each geographic division from March 11 to April 21, 1928, compared with corresponding period of 1927

Geographic division	1928			1927		
	Mar. 11-24	Mar. 25-Apr. 7	Apr. 8-21	Mar. 13-26	Mar. 27-Apr. 9	Apr. 10-23
Total (95 cities)	245	250	232	205	185	175
New England	218	215	180	177	158	168
Middle Atlantic	275	284	269	236	215	208
East North Central	226	256	223	158	151	149
West North Central	145	143	198	125	125	143
South Atlantic	226	222	218	312	227	212
East South Central	374	418	285	284	265	223
West South Central	375	310	285	188	191	115
Mountain	292	168	198	188	233	165
Pacific	122	117	88	123	143	119

Meningococcus meningitis.—The total cases of meningococcus meningitis reported by 42 States in the four weeks ended May 5 numbered 538 as against 578 in the preceding four-week period and 249 in the corresponding period of 1927. While the number of new cases reported in most States has shown little change in recent weeks, a rather marked decline occurred in a number of the Western States where the incidence of the disease had been relatively high. In Colorado the number of reported cases dropped from 54 in the four weeks ended April 7 to 22 in the four weeks ended May 5; in Arizona the number dropped from 17 to 7; in Arkansas from 10 to 3; in Oklahoma from 15 to 8; in Texas from 8 to 3; in Utah from 16 to 9; and in Oregon from 14 to 6. On the other hand, the number of cases reported in New York State increased from 108 to 176.

Smallpox.—A gradual seasonal decline in the number of smallpox cases reported by 42 States was apparent in the returns for the four weeks ended May 5, the total number reported for the period being less than 3,900—a decline of approximately 900 from the preceding four-week period. The reported cases for these four weeks numbered about 1,000 more than for the corresponding period of each of the preceding two years. Some decline has occurred in nearly all the States; only Montana reported a definite increase, the number increasing from 52 in the four weeks ended April 7 to 99 in the four weeks ended May 5. In all the States in which an increased prevalence was noted in the four weeks ended April 7, a decrease was reported in the following four weeks, the decreases being especially marked in California, Colorado, New Mexico, Missouri, Indiana, and West Virginia. In Oklahoma, where smallpox has been prevalent in recent months, the number of reported cases dropped to 192 in the two weeks ended May 5, as against 340 in the preceding two weeks.

Scarlet fever.—A seasonal decline in the incidence of scarlet fever during April was evident from the reports for 41 States, which showed a total of 3,900 cases in the week ended May 5 as compared with about 4,900 in the week ended March 31. The number of cases reported by Massachusetts, Connecticut, New York, New Jersey, and Pennsylvania in the four weeks ended May 5 indicated a definite decline as compared with the preceding four-week period in these States, and smaller decreases occurred in most of the remaining States. Montana and Wyoming reported a slight increase, but the number of cases was small.

Diphtheria.—The number of cases of diphtheria reported weekly by 42 States has declined steadily since early in February, and in the week ended May 5 there were 1,300 cases reported as compared with 1,450 in the week ended April 7 and with 1,833 in the week ended March 3. The disease is still somewhat more prevalent than it was in 1926, but only slightly more so than it was in 1927.

Measles.—The total number of cases of measles reported by 38 States showed little or no change during March and April; the weekly number of cases reported was approximately 18,000. In general, the incidence of the disease has been higher in the current year than it was last year in the New England, Middle and South Atlantic, and East South Central States, but it has been lower than it was a year ago in the North Central, Mountain, and Pacific States. Among the States showing a rather high incidence the following reported an increase in the two weeks ended May 5 as compared with the preceding two weeks: Arkansas, Florida, Georgia, Louisiana, Tennessee, Kansas, Missouri, Indiana, Pennsylvania, New Jersey, New York, and Rhode Island. On the other hand, a decrease in cases was reported by Alabama, Maryland, Massachusetts, Michigan, North Carolina, New Mexico, and Texas. Measles epidemics are local in character and may occur at almost any season, but a general decline in prevalence should take place in May, and the summer months may be expected to bring the incidence to a low level.

Typhoid fever.—The typhoid fever incidence continued lower in April than in the same month for either of the preceding two years. No State reported as many as 20 cases a week in March or April, and the weekly case rates for 101 cities (annual basis) varied from 4 to 6 per 100,000 population, which is lower than the rates for any of the preceding four years at this season. The incidence rates have been higher in the South Atlantic and South Central States than in the remainder of the country, but have been favorable in these geographical districts as compared with earlier years.

Poliomyelitis.—The number of cases of poliomyelitis continued to decline during April, and 81 cases were reported by 43 States in the

four weeks ended May 5 as compared with 107 in the preceding four-week period. Of the 81 cases reported, 23 were in California, and no more than 5 in any other State.

Foreign Countries [1]

The general prevalence for certain epidemic diseases in most foreign countries during February and March is summarized below.

Plague.—Eight plague cases were reported during the second half of March in Ben Gardane district in southern Tunis near the Tripoli frontier. Tunis had been free from plague since August, 1927, and these cases occurred a long distance from the scene of the outbreaks of 1926–27. Algeria and Greece were both free from plague in February and March.

Plague cases continued to occur at Suez in March; 30 cases were reported from the beginning of January up to April 7. Only three plague cases have been reported elsewhere in Egypt since the beginning of the year—one at Alexandria and two in Upper Egypt.

The outbreak at Aden increased during March, and 462 cases were reported in the three weeks ended April 7, as compared with 424 cases in the preceding three weeks. In the week ended April 14, there were 108 cases reported, indicating a slight decline in new cases. From the beginning of the outbreak to April 14, 1,300 cases and 943 deaths had been reported. During the whole of the epidemic in 1900, which hitherto had been the most severe, 708 cases and 576 deaths were reported.

Plague spread rapidly in India in the beginning of February, 1928. During the week ended February 4, 4,517 cases and 3,296 deaths were reported, as compared with 1,394 cases and 967 deaths during the corresponding week of the preceding year. The number of plague cases and deaths reported between the middle of December and the middle of February was practically the same, week for week, as that reported during the corresponding period of 1925–26, a year of moderately severe plague prevalence.

The accompanying table shows that, in comparison with 1926, the plague situation in February, 1928, was rather bad in the United Provinces, Hyderabad, and Burma, but very good in the Punjab and in Bihar. The severe outbreak at the city of Hyderabad began to decline early in February. In upper Burma the spread of plague appears to have come to a standstill except in the town of Mandalay.

[1] Data from the Monthly Epidemiological Report of the Health Section of the League of Nations' Secretariat, Apr. 15, 1928, supplemented by information published in the PUBLIC HEALTH REPORTS.

Deaths from plague in the Provinces of India during the first six weeks of 1926, 1927, and 1928

Provinces	1926		1927		1928	
	Jan. 3-23	Jan. 24-Feb. 13	Jan. 2-22	Jan. 23-Feb. 12	Jan. 1-21	Jan. 22-Feb. 11
Punjab, Delhi, and Punjab States	1,426	3,142	392	460	200	294
United Provinces	1,920	2,910	1,134	1,062	2,203	3,884
Bihar and Orissa	380	659	326	498	190	350
Central Provinces	344	478	413	495	366	569
Madras Presidency	259	275	210	153	197	224
Hyderabad	348	700	91	68	1,854	1,771
Mysore	329	365	151	84	58	64
Bombay Presidency	598	663	135	134	308	397
Burma	438	488	157	285	890	1,161
Other Indian States	162	242	63	61	21	63
Total	6,204	9,922	3,072	3,300	6,296	8,777

In the United Provinces the outlook is somewhat disquieting, the number of plague cases and deaths reported having trebled from the week ended January 28 (757 deaths) to the week ended February 18 (2,329 deaths). Such a rate of increase, at this time of the year, has not been seen in the United Provinces since 1918; the nearest approach was in 1924, when the number of deaths attributed to plague doubled during the corresponding three weeks.

Plague is slightly more prevalent in Java than it was in 1926, but less so than in 1924 and 1925. During the 12 weeks ended January 28, 1928, there were 2,604 deaths attributed to plague, as compared with 2,175 during the corresponding period of the preceding year. Central Java continues to be most heavily infected, but western Java has not escaped.

The actual incidence of plague in the east African centers of plague in Kenya, Uganda, and Madagascar is about the same as it was early in 1927. In Madagascar, 705 deaths were ascribed to plague during the first two months of 1928, as compared with 749 during the corresponding period of the preceding year. No plague case has been reported either in Mauritius or in Réunion since early in 1927.

In the Union of South Africa, 17 plague cases were reported on inland farms from the beginning of the year to March 24.

The plague season has not yet begun in the west African centers, but there have been a few cases at Lagos and Ijebu in Nigeria (37 cases up to March 10), and in Senegal (25 up to March 20).

Cholera.—The incidence of cholera was above normal at Calcutta in March, the disease having been very prevalent in Bengal during the winter. There was no cholera in ports west of Bombay.

Cholera in India, though slightly less prevalent in February than in January, caused about the same number of deaths as in the corresponding month of the two preceding years, but more than during the corresponding periods of 1922–25. During the three weeks ended February 18, 1928, 4,802 deaths were attributed to cholera, as compared with 4,331 deaths in 1927. The disease was almost entirely confined to the two most persistent centers—(1) Bengal, with Assam and Orissa, and (2) Madras Presidency.

Cholera cases and deaths in maritime towns of the Far East in March, 1926, 1927, and 1928, reported to the Singapore Bureau

Port	1926		1927		1928

Manila	2	0	0	0	0	0
Canton			0	0	1	1

In Siam, 395 cases were reported during the first eight weeks of 1928, as compared with 326 and 1,168 cases during the corresponding periods of 1927 and 1926, respectively. During the first eight weeks of each of the years from 1922 to 1925 only from 2 to 13 cholera cases were reported weekly in the whole country.

During the first quarter of 1928, cholera was prevalent in the southern part of French Indo-China, 220 cases being reported in Cambodia, 1,162 cases in Cochin-China, and 376 in Annam up to March 20. Tonkin and Laos were reported free from cholera.

Yellow fever.—In the Belgian Congo, there was one yellow fever case at Matadi on February 24 and one case on board a ship at Boma on March 5. No other case was reported there or elsewhere in Africa in March.

Smallpox.—Cases of smallpox were rare in most countries on the European continent early in 1928. No case was reported in Bulgaria, Czechoslovakia, Denmark, Gibraltar, Hungary, Lithuania, Luxemburg, and Rumania either in January or February; in Sweden up to March 15; in the Kingdom of the Serbs, Croats, and Slovenes up to March 21; nor in the Irish Free State, Northern Ireland, Scotland, and Switzerland up to March 24. Malta and Norway were both free from smallpox in January. Estonia, Finland, and Latvia each had reported one case in the first two months of the year; Belgium

reported one case up to March 24, and Germany one case up to March 10. Poland reported three cases up to March 10, and Italy three cases in the first two weeks of the year.

Greece, with eight cases of smallpox reported up to the end of February, and France, with 21 cases in the same period, showed marked improvement over the corresponding months of 1927, when they reported, respectively, 36 and 108 cases.

Portugal reported 258 smallpox cases with 30 deaths in the first two months. No information was available for Spain or for the Union of Soviet Socialist Republics.

In England and Wales smallpox was less prevalent in the first 12 weeks of the year than in the corresponding period of 1927; 4,377 cases were reported as compared with 5,774 in 1927.

Marked improvement in the smallpox situation in northern Africa is indicated by the early reports for 1928. In Algeria 174 cases had been reported up to March 24 as against 518 cases in the period of 1927; in Egypt only 2 cases up to February 11 as against 121; and in French Morocco 97 cases up to February 29 as compared with 265. In Tunis a slight increase occurred, and 39 cases were reported up to March 18 as compared with 26 in the corresponding period of 1927.

The severe form of smallpox persisted in northern Rhodesia in 1928; 388 cases and 46 deaths were reported up to February 4, and 297 cases and 42 deaths in the next five weeks.

There was an increase of smallpox cases in India after the middle of January, 18,336 cases being reported during the four weeks ended February 18 as compared with 12,668 cases in the preceding four weeks. The incidence was not quite as high, however, as in the preceding year, when 23,282 cases were reported during the four weeks ended February 19.

Typhus fever.—The serious outbreak of typhus fever which began last year in Morocco persisted unabated in the early months of 1928. Up to March 24, 2,464 cases were reported as compared with 484 during the corresponding period of the preceding year. The principal center of the disease is in the southern part of the country, especially at Marrakesh and in the Sous area, the principal town of which, Taroudant, has suffered most severely. During the period under review, 940 cases were reported in the town of Taroudant, which has about 8,000 inhabitants. There were 527 cases at Marrakesh and 218 at Casablanca. Unfavorable economic conditions resulting from the poor harvests of 1926 and 1927 in the part of the country south of the great Atlas Mountain Range has undoubtedly predisposed the population to the epidemic which is here of a severe type. It is said that typhus elsewhere in Morocco is usually of a relatively mild type.

In eastern Europe the typhus situation was satisfactory in the early part of 1928. In Poland 738 cases were notified up to March 10, as compared with 825 during the corresponding period of 1927. In Lithuania an increase occurred, and 223 cases were reported in January and February as compared with 46 cases in the first two months of last year. No reports were available for 1928 for the Union of Soviet Socialist Republics, but fewer cases were reported for the fourth quarter of 1927 than in the preceding years.

Influenza.—Influenza was little in evidence in Europe during the first quarter of 1928. Although minor outbreaks may occur in April or May, there is every indication that 1928 will be a year with low influenza incidence, comparable with 1921 or 1926.

In large towns of England and Wales the number of deaths attributed to influenza decreased in January, and then remained more or less stationary up to the middle of March; 270 deaths were reported during the two weeks ended March 31, as compared with 209 deaths during the preceding two weeks. During the first quarter of 1928, 1,467 deaths were ascribed to influenza, as against 7,477 during the first quarter of 1927. There was no increase of the general death rate during the period under review.

Mortality statistics of large German towns showed no evidence of influenza outbreaks up to March 10. During the first 10 weeks of 1928 there were 481 deaths ascribed to influenza; in the corresponding weeks of 1927 the number was 3,256.

Returns of influenza cases reported in Denmark, Norway, Sweden, and Finland showed a low prevalence of this disease in January and February. Very few deaths from influenza were reported in Polish towns during these months; at Warsaw, there were 7 deaths from this cause during the four weeks ended March 24. In Vienna 4 deaths were attributed to influenza in January and 16 deaths in Budapest during the four weeks ended March 24.

In Switzerland, only 65 deaths were ascribed to influenza in January, as compared with 1,648 during the corresponding month of 1927. In the Netherlands, 147 deaths were attributed to influenza in January, as against 2,015 in the corresponding month last year.

In Paris, there were 74 deaths from influenza in January, 62 in February, and 26 during the first 20 days of March; statistics for other French towns showed but little prevalence of the disease. There were very few deaths from influenza in Italian towns in January and February.

CURRENT STATE MORTALITY STATISTICS

For the information of public health officials and others interested, the data in the following tables have been taken from the monthly mortality reports of State health departments for the latest month for which published records are available. Statistics of most communicable diseases are not included, since they are available in other tabulations in the Public Health Reports. Statistics of deaths from other causes are limited for the most part to those causes which appear in the State reports. In the case of States which publish detailed mortality reports each month, the record of only the principal groups of causes and certain important specific causes have been used.

For purposes of comparison, the mortality records for the corresponding month in a few preceding years have been compiled. The rates have been computed upon the populations as estimated for July 1 of each year represented.

These tabulations will be enlarged as the current data on mortality from additional States become available.

Summaries of annual mortality statistics for the year 1927 are appended whenever the data are available from the States, and comparisons with several prior years are included when practicable.

IOWA AND NORTH CAROLINA

MARCH, 1928

Death classification by cause or age	Iowa	North Carolina
Annual rate per 1,000: 1-205. All causes	12.1	(1)
Rate per 1,000 live births: Infant mortality	66.4	(1)
Annual rate per 100,000:		
11. Influenza	79.5	63.7
31- 37. Tuberculosis, all forms	88.8	86.6
43- 49. Cancer and other malignant tumors	121.2	
57. Diabetes mellitus	19.9	
70- 86. Diseases of the nervous system and of the organs of special sense	153.2	
74. Cerebral hemorrhage, apoplexy	111.5	
87- 96. Diseases of the circulatory system	310.8	
87- 90. Diseases of the heart	279.8	
97-107. Diseases of the respiratory system	105.2	
100-101. Pneumonia (broncho and lobar)	98.4	168.7
108-127. Diseases of the digestive system	65.5	
113. Diarrhea & enteritis (under 2 years)	5.8	10.0
128-142. Nonvenereal diseases of the genito-urinary system	64.5	
128, 129. Nephritis, all forms	53.8	
143-150. The puerperal state	11.2	
151-158. Diseases of the skin and of the bones and organs of locomotion	2.9	
159-163. Malformation and diseases of early infancy	61.1	
165-203. External causes	83.9	
165-174. Suicides (total)		6.0
188c. Automobile accidents	12.1	8.8
197-200. Homicides		8.0
Number of deaths:		
Under 1 year	236	
1 to 4 years	66	
5 to 64 years	927	
65 years and over	1,265

LOOSELY BOUND SULPHUR IN PITUITARY EXTRACTS

By M. X. Sullivan, *Biochemist*, and M. I. Smith, *Senior Pharmacologist, Hygienic Laboratory, United States Public Health Service*

INTRODUCTION

The rôle which sulphur, especially organically combined sulphur, plays in the economy of the animal body, and that of man in particular, has been greatly emphasized by the work of Hopkins (1921) and that of Abel and Geiling (1926). Thus, Hopkins succeeded in isolating glutathione, a peptide of cysteine and glutamic acid, from mammalian muscle and liver as well as from yeast, and concluded that this sulphur-containing peptide is the most important autoxidizable constituent of the cells. Abel and Geiling (1926) gave a fresh impetus to the study of sulphur when they demonstrated the high degree of lability of the sulphur in insulin and the relation of the loosely bound sulphur to the potency of insulin in lowering blood sugar.

Abel and Geiling found that the sulphur in insulin is liberated by short boiling with 0.1 N sodium carbonate, and that the amount of the "sodium carbonate sulphur" is directly proportional to the degree of hypoglycemic activity.

In later work with crystalline insulin du Vigneaud (1927) found that when it is split by acid hydrolysis cystine is found in the hydrolysate, as evidenced by the positive reaction with the Sullivan (1926) cystine test, which has been found highly specific for cystine or substances structurally like cystine. Du Vigneaud considers that insulin is most likely a derivative of cystine or of a compound like cystine.

Since insulin is the material elaborated by an endocrine gland, the islands of Langerhans, it became of interest to us to determine whether the active principle of other endocrine glands, as, for instance, the pituitary, contained cystine or cystinelike compounds, since, chemically speaking, little is known regarding the chemical nature of the active material of the pituitary gland.

The chemical study of the pituitary active principle is hampered by its instability and by the difficulty of getting a sufficient supply of material.

The pituitary body is divisible morphologically into two parts—anterior and posterior. From the posterior lobe extracts have been obtained which are endowed with various physiological activities such as stimulation of uterine contraction (oxytocic activity), augmentation of the blood pressure (pressor activity), and action on the kidney (renal activity).

The question as to whether the various activities of the posterior pituitary are due to one and the same active principle has long been

a moot one. Abel and Rouiller (1922) concluded that there is but one active principle, which, in its uninjured state, is not only a blood-pressure raising, but also is a plain-muscle-stimulating substance. This view has been consistently maintained by Abel and his associates, and evidence in favor of it is well reviewed by Abel (1924). Smith and McClosky (1924) likewise give evidence favoring a single active principle. On the other hand, other investigators, among whom may be mentioned Fühner in Germany (1913) and, especially, Dudley in England (1923), offer evidence suggesting the presence of more than one active principle.

Recently Kamm, Aldrich, Grote, Rowe, and Bugbee (1928) have apparently succeeded in separating two active principles from the posterior lobe of the pituitary gland, one of which raises blood pressure and another which stimulates contraction of the uterine muscle.

PHYSIOLOGICAL AND CHEMICAL TESTS OF EXTRACTS

The criterion of activity mainly relied on by us was the ability of the extract to raise the blood pressure when injected intravenously into an anesthetized dog.

The material which we have used in this work consisted of 21 samples of posterior pituitary and 12 samples of anterior pituitary. The pituitary preparations comprised the following.

1. Five samples of standard powdered pituitary (K_2, I_2, J_2, M_2, N_2) which had been prepared by Smith and McClosky (1924) in the course of their work on the standardization of pituitary extracts.
2. A fresh gland extract (D), 1 cubic centimeter of which represented the physiological activity of 7 milligrams of standard powdered pituitary.
3. A sample of a commercial powdered posterior pituitary (L) which, when assayed in this laboratory, was found to be of standard potency.
4. Two commercial samples—one labeled hypophysis cerebri (M), the other labeled desicated posterior pituitary (E). Both of these samples were physiologically inert.
5. A commercial sample of "pituitary body desiccated" (A), having a slight and almost negligible oxytocic activity.
6. Eleven commercial samples of posterior pituitary presumably made to conform to the U. S. P. X requirements. This material was kindly furnished by W. T. McClosky of the pharmacological laboratory of the Bureau of Food, Drug, and Insecticide Administration.
7. Twelve commercial samples of desiccated anterior pituitary furnished through the same source.

Extracts from these samples were made according to the U. S. P. X method of preparing extracts from standard pituitary. The pituitary powder was ground in an agate mortar with 10 cubic centimeter of 0.25 per cent acetic acid. The mixture was collected in pyrex test tubes and carefully brought to gentle boiling and filtered. The clear filtrates were then used for chemical and physiological

tests. In most cases 1 cubic centimeter of the extract represented 10 milligrams of pituitary powder. In some cases of potent extracts 1 cubic centimeter of solution represented only 5 milligrams of posterior pituitary powder, while with slightly potent powders and with the anterior, extracts were often used in which 1 cubic centimeter represented 20 milligrams of powder.

The pressor physiological activity, where indicated, was determined by the procedure described by Smith and McClosky (1924). Some observations have been made on the oxytocic power of the extracts by W. T. McClosky, to whom we are indebted. His findings have, in general, agreed with the pressor tests. The oxytocic study, however, will be reserved for a future publication in which the two physiological activities as measured by the pressor and oxytocic methods will be correlated quantitatively with the chemical reaction about to be described. For the present, as stated previously, the criterion of activity used by us is the power to raise the blood pressure when injected intravenously into a dog.

In the chemical work with the extracts a preliminary investigation was made to see whether any cystine or cystine complex was present in the standard extract. The unhydrolyzed extract gave a negative reaction for cysteine and cystine as determined by the Sullivan method. On hydrolysis for four hours with 20 per cent hydrochloric acid and bringing the hydrolysate to 0.1 N hydrochloric acid, a positive reaction for cystine or cystinelike compounds was obtained. While the hydrolysis was progressing, some tests were made on small amounts of the active extract for so-called loosely bound sulphur—that is, the formation of lead sulphide when heated with lead acetate and sodium hydroxide, along lines first laid down by Fleitmann (1848) in this work on the sulphur of proteins. This test proved to be decidedly positive; and since it required very little active extract and could be done speedily, attention was given to it, temporarily, rather than to the more time-taking cystine test. From application of the loosely bound sulphur test to the various extracts, an interesting relationship was indicated between the presence of highly reactive sulphur and physiological activity.

The expression "loosely bound sulphur" needs some explanation. It is a relative term and merely means that the sulphur is in a labile state and is more or less easily split off. The more dilute the alkali, the lower the temperature, and the shorter the time needed to split off the sulphur in the compound, the more labile is the sulphur. Compounds differ greatly in this respect. Cystine complexes, as, for instance, cystine in peptide arrangement, have a much more reactive sulphur than uncombined cystine, as first noted by Fischer

and Gerngross (1909). Isocystine as given by Gabriel (1905) is much more labile than cystine obtained from keratin by hydrolysis. We have at present in this laboratory organic sulphur compounds not related to cystine which will liberate sulphur with very dilute alkali and no heating.

After some experimenting the following test for loosely bound sulphur in pituitary extracts was evolved. To 2 cubic centimeters of the dilute acetic acid extract in a small test tube, there were added 0.1 cubic centimeter of half-saturated or saturated lead acetate solution and 1 centimeter of sodium hydroxide (usually normal), and the tube was placed in boiling water. Potent extracts begin to brown in 15 seconds and give a black precipitate within two to five minutes, while inactive preparations do not show such a coloration even if kept in boiling water for 15 minutes. Extracts of five samples of standard powdered pituitary, prepared at the Hygienic Laboratory, and earlier referred to as preparations K_2, I_2, J_2, M_2, and N_2, gave a speedy and decisive precipitation of lead sulphide. The fresh gland extract (D) behaved likewise.

The first trials were carried out with 5 N sodium hydroxide. These tests demonstrated (1) that the acetic acid extracts of the posterior lobe contained reactive sulphur, as evidenced by the quick formation of lead sulphide; (2) that extracts of the anterior lobe contained little if any highly reactive sulphur, though in a few cases they did contain sulphur demonstrable by boiling with strong sodium hydroxide; (3) that the reactive sulphur appeared to stand in some relation to physiological activity, since extracts of inactive posterior powders failed to give the sulphide reaction.

TABLE 1.—*Loosely bound sulphur in posterior pituitary extracts (using 5 N sodium hydroxide)*

Using 5 N sodium hydroxide and a short heating period (2 to 5 minutes), the lead sulphide test was carried out on extracts of 16 samples of posterior pituitary powders and similar extracts of 12 anterior lobe preparations. Of the 16 posterior lobe preparations listed in Tables 1 and 2, the extracts of 12 gave a strong lead sulphide precipitate in from 1 to 3 minutes, 2 gave a faint reaction, and 3 were negative.

The posterior lobe extracts A, E, and M of Table 1, which gave a negative lead sulphide test, proved to be physiologically inert. Of the two extracts giving a faint lead sulphide test, one, No. 1469, showed but a trace of activity, physiologically, while the other, No. 1592 (Table 2), showed about 30 per cent activity as compared with a standard extract.

Sample No. 1592, which gives, as far as qualitative judgment goes, only a slight sulphide reaction, has as good physiological activity as some other samples which have given a strong lead sulphide test. While calling attention to this anomaly in our work we reserve judgment for further study of a quantitative nature.[1] Of the extracts of the 12 anterior powders, 9 were entirely negative, while 3 gave a definite positive test. The anterior extracts which gave indications of a positive lead sulphide test were tested physiologically and were found devoid of pressor activity.

As previously stated, the more dilute the alkali used and the shorter the time necessary to give a positive lead sulphide test in the presence of lead acetate, the more labile is the sulphur in question. Since heating with 5 N sodium hydroxide would split off more or less sulphur from compounds, such as cystine, which, in the light of recent work on labile sulphur, have only a slight lability, the chemical tests were repeated with weaker alkali. As a result of numerous experiments, it was found that N sodium hydroxide was very satis-

[1] The occurrence of nonspecific pressor amines may be mentioned as a possible cause of the discrepancy.

factory for the demonstration that extracts of the posterior lobe of the pituitary gland contained highly reactive sulphur. Thus, as shown in Table 3, with this modification of the test the extracts of the anterior lobe gave no reaction for highly reactive sulphur, while the extracts of the posterior lobe gave a sharp distinctive precipitation of lead sulphide within five minutes' heating.

As may be seen from Table 4, extracts of standard powders give a quick and sharp lead sulphide reaction, certain extracts, inactive physiologically, give little if any lead sulphide, and the commercial powders are less reactive than the standard powders, both physiologically and chemically. The work with the various samples of posterior pituitary is taken as a strong suggestion that a close relationship holds between the reactive sulphur and the physiological activity.

Cystine (0.5 milligram per cubic centimeters of 0.1 N hydrochloric acid), under the conditions given in Table 3, does not give a positive lead sulphide test. After 10 minutes' heating, cystine shows only a trace, if any, of lead sulphide. Glutathione, on the other hand, a peptide of cystine and glutamic acid in a concentration of only 1 milligram per cubic centimeter 0.1 N hydrochloric acid, gives a quick, sharp lead sulphide test.

It would seem that, in contrast to extracts of the anterior lobe or of inactive posterior lobe powders, the extracts of the active posterior lobe powders contain a peptide type of sulphur perhaps of the glutathione type. The less reactive sulphur, demonstrable in some cases of anterior lobe extracts (with the use of strong alkali or long boiling), must belong in all probability to more stable sulphur compounds.

INACTIVATION OF EXTRACTS BY HEATING WITH HYDROCHLORIC ACID

Abel and Nagayama (1920) found that pituitary extracts acidified to the extent of 0.5 per cent hydrochloric acid and boiled for half an hour lost practically all of their physiological activity. Accordingly, an experiment was made by us to determine what effect heating an active extract with 0.5 per cent hydrochloric acid would have on the reactive sulphur. Eight cubic centimeters of a 1 per cent extract of standard powdered pituitary, which gave a prompt and strong lead sulphide test, were treated with 0.21 cubic centimeters of 20 per cent hydrochloric acid to form a solution containing approximately 0.5 per cent hydrochloric acid. This solution was boiled for one hour under reflux condenser. Two cubic centimeters of the boiled solution in a small test tube were treated in the usual manner with 0.1 cubic centimeter half-saturated lead acetate solution and 1 cubic centimeter N sodium hydroxide, and the tube was placed in boiling water. A strong positive sulphide reaction occurred within three minutes. Physiologically, however, the extract was found to have lost most of its activity by the heating with 0.5 per cent hydrochloric acid.

If it is assumed that the reactive sulphur of post-pituitary extracts is not an incidental matter, but is rather directly associated with the physiological activity of the gland, then the discrepancy just noted—the loss of physiological activity on heating with dilute hydrochloric acid without noticeable effect on the lead sulphide reaction—must be explained. A possible explanation is that the active principle is a complex, one part of which contains labile sulphur. The labile sul-

phur part is not injured by the short heating with the dilute acid, while other components of the complex, essential for the known activity, are either split off or are chemically changed. This phase of the question we can not deal with now, but shall content ourselves by stating the fact that heating with dilute acid inactivates the extract but does not destroy the groups containing highly reactive sulphur.

SUMMARY

As the investigation stands, the tests on extracts of the posterior pituitary lobe showed that they contained highly reactive sulphur (reactive in the presence of N sodium hydroxide), while extracts of the anterior lobe did not. Secondly, certain extracts of the posterior lobe, which were found to have little or no physiological activity, were negative in the lead sulphide test. Of the many tests made, one posterior lobe extract (No. 1592) gave an anomalous reaction in that it gave only a slightly positive lead sulphide test, while physiologically it was found to be relatively fairly active. In general, there was a very remarkable agreement between the physiological test, as measured by the rise in blood pressure when injected into anesthetized dogs, and the chemical test—that is, quick formation of lead sulphide when heated with N sodium hydroxide and lead acetate.

Whether this agreement is coincidental or is an indication that the physiological activity of the posterior pituitary is tied up with the presence of highly reactive sulphur compounds must remain for further investigation, of a quantitative nature, which is now being planned. In either case the test for highly reactive sulphur should be useful in the isolation and purification of the active principles.

COURT DECISION RELATING TO PUBLIC HEALTH

Sewer district act held constitutional.—(Missouri Supreme Court; State ex rel. Gentry, Atty. Gen., *v.* Curtis et al., Sup'rs of Webster Groves General Sewer Dist. No. 1 of St. Louis County, 4 S. W. (2d) 467; decided March 17, 1928.) An act approved March 25, 1927 (Missouri Laws 1927, pp. 439–465), authorized the formation of sewer districts in counties having 75,000 or more population. A quo warranto proceeding was brought to oust certain persons as supervisors of a sewer district, it being contended that the above-mentioned act, under which the supervisors held office, was unconstitutional. Numerous grounds of unconstitutionality were urged, but the supreme court ruled against them all, thus holding the law to be a valid enactment.

PUBLIC HEALTH ENGINEERING ABSTRACTS

We Want Pure Air in Our Towns. Louis Forest. *The World's Health*, vol. 9, No. 3, March, 1928, pp. 86–88. (Abstract by Leonard Greenburg.)

The author feels that we should make an effort to furnish city dwellers with pure air just as we furnish them with pure water. On March 22, 1926, he says, two members of the French Academy presented the following analysis of material which fell on a gauge placed in the center of Paris:

	Grs per square meter
Carbon	2.659
Hydrocarbons	1.824
Sulphuric acid	2.432
Chlorine	.253
Ammonia	.021

A further analysis made at Vitry disclosed 1.592 kilograms of soot to the square meter during the month of February. The author ascribes this latter figure to the use of coal rich in ash. The reaction of the distillation by-products of coal with Paris water which has been purified by chlorine is such as to produce an iodoform taste in the water sufficient to render the liquid, at times, undrinkable, according to the author.

A draft law has been brought before the Chamber of Deputies which will permit the authorities to proceed to study this problem and remedy the present state of affairs.

Quantitative Measurements of the Inhalation, Retention, and Exhalation of Dusts and Fumes by Man: I. Concentrations of 50 to 450 Milligrams per Cubic Meter. P. Drinker, R. M. Thomson, and J. L. Finn. *Journal of Industrial Hygiene*, vol. 10, No. 1, January, 1928, pp. 13–25. (Abstract by Leonard Greenburg.)

The purpose of this study was to determine quantitatively the retention of certain representative dusts and fumes by the lungs of persons forced to respire them. Zinc oxide of a particle size of 0.4 microns, Kadox, which is zinc oxide having a particle size of 0.15 microns, and marble dust, having a particle size of 0.3 to 6 microns, were utilized as the representative dusts. Each of these dusts was set up in a 1,600-cubic-foot gas cabinet. The subjects were seated outside of the cabinet and derived their supply of air containing the dust from the cabinet. The quantity of dust which was exhaled was determined by means of an electric precipitator, while the volume of air was found by the use of a spirometer. Concentrations of dust from 50 to 450 milligrams per cubic meter were used with exposures of from 5 to 40 minutes and with respirations from 6 to 18 per minute. Under these conditions the percentage retention for all three dusts averaged 55, with a standard deviation of 9.4 This study appears to be a very excellent and accurate piece of work.

Studies in School Ventilation. R. F. Heath and J. S. Patterson. *Contract Record and Engineering Review*, vol. 42, No. 1, January 4, 1928, pp. 8–13. (Abstract by R. E. Thompson.)

A description and discussion of observations made in a school building in Toronto. The heating equipment consists of low-pressure boilers for heating by direct radiation only. The ventilation vent, housed in the basement, comprises tempering coils, air washer of spray type, reheater and fan, with ducts to each room. Ozone can be introduced between the tempering coils and the washer. The air can be recirculated, or fresh air can be introduced into the system. The observations made included temperature, humidity, and wet and dry kata thermometer readings. The effects noted of temperatures above the "effective temperature" are described. Odors are not removed to any great extent by the air washer. Introduction of 0.013 p. p. m. of ozone effected some improvement, but did not eliminate all odors.

Atmospheric Pollution with Arsenical Dust. G. Sowden. *The Journal of State Medicine*, vol. 35, No. 11, November, 1927, pp. 668–670. (Abstract by Leonard Greenburg.)

This study arose because of a complaint that the dust from a power generating station was a nuisance and that it contained arsenic to the extent of 125 parts per million. Accordingly, samples of dust were taken from the roof, rain-water gutters, and chimney shaft of the power plant and several factories in the neighborhood. The pulverized coal used at the power plant contained but 3 parts of arsenic per million, whereas the samples from the roof of the plant contained from 50 to 175 parts, from rain-water gutters from 100 to 200 parts, and from flue dust from 7 to 500 parts. In spite of the fact that the pulverised coal apparently contained so little arsenic, it is the author's belief that all of this arsenic

originated in the coal that was being burned. It is pointed out that various types of coal may contain considerably larger amounts of arsenic than found here.

The question arises as to the health hazard brought about by the presence of this amount of arsenic in the furnace dust discharged in the atmosphere. It is conceivable that a workman might inhale more than that amount of arsenic which is specified as being the maximum permitted on imported apples. The requirements for apples at the present time specify that more than one one-hundredth of a grain of arsenic per pound of apples is undesirable. The author concludes that workmen engaged in cleaning out furnace flues would doubtless inhale more than this quantity of dust, but, on the other hand, there appears to be no knowledge of any injury having arisen from this cause.

In conclusion, the author points out that the public health smoke abatement act should tend to lessen atmospheric pollution of this nature.

Experiments on the Ventilation of Small Bedrooms. A. H. Barker. *Gas. J.* 180, 193–5; *Gas World* 87, 359–60 (1927). Abstract by R. W. Ryan in *Chemical Abstracts*, vol. 22, No. 1, January 10, 1928, p. 130.

"Three men slept in a room of 1,200 cubic feet capacity. At the start of the night the CO_2 content of the air was 4 parts per 10,000. With no ventilation the CO_2 increased to 27 parts per 10,000; with a window open 3 inches, to 20 parts; and with the window open 12 inches, to 11 parts, CO_2 per 10,000. With a small gas heater in a fireplace, connected with a chimney, the CO_2 increased to only 8 parts per 10,000."

The School Ventilation Study in Syracuse, New York. Thomas J. Duffield. *American Journal of Public Health and the Nation's Health*, vol. 18, No. 3, March, 1928, pp. 326–330. (Abstract by Leonard Greenburg.)

In this study the efficiencies of window and mechanical ventilation are contrasted on the basis of the respiratory disease associated with their use in the schools of Syracuse, N. Y.

Six schools, three of each type, were studied over the winter period 1926–27. The author brings out the fact that unless the factors of race and age are approximately equal in both types of schools one is not warranted in drawing a conclusion from rates of respiratory illness absenteeism that one type of ventilation is more favorable than the other. Because the original two groups of 3 schools each were not balanced in these respects, the author, by eliminating 2 schools, leaving a resultant group of 4, has balanced up these factors. The resulting group of four schools yielded the following results:

Consolidated attendance and health records in two mechanically ventilated and two naturally ventilated schools in which the effects of race and age are approximately balanced

	Mechanically ventilated schools [1]	Naturally ventilated schools [1]	Excesses in mechanically ventilated schools
			Per cent
Total absences	7.0	5.4	29
Absences due to respiratory illness	2.9	2.2	32
Respiratory illness among pupils present	8.8	7.8	13
All respiratory illness	11.7	10.0	17

[1] Per cent of total pupil sessions.

The author closes by pointing out that even with this somewhat refined treatment of his data one is hardly warranted from his study in drawing the conclusion that natural ventilation of schools is more healthful than mechanical ventilation.

Failure of Slow Sand Filtration in Madras City.—J. W. Madeley. *The Surveyor*, vol. 72, No. 1873, December 16, 1927, pp. 593–595. (Abstract by R. E. Thompson.)

This article gives a description of the water works of Madras, India, and of the difficulties experienced in the operation of the slow sand filters, together with an outline of suggested improvements. The source of supply is Red Hills Lake, situated 7 miles from the filter plant. The numerous villages situated on the watershed have no drainage systems, and during the rainy seasons their filth is washed directly into the lake without treatment. The water, consequently, is of poor quality. Vibrios have been found on a number of occasions. The average rainfall is 37 inches per annum. The water works were constructed to supply 25 gallons of water per capita per day, to a population of 660,000, and consist of an intake tower, a 7-mile underground conduit of concrete and brickwork, 17 open slow sand filters with total area of 8¼ acres, 4 underground filtered-water tanks with total capacity of 6.5 m. g., a 1.5 m. g. elevated steel balancing tank, and a cast-iron pipe distribution system throughout the city. Most of these works were put in commission about 1914–15.

Filters Nos. 1–14 are each 200 by 100 feet, and Nos. 15–17 are 200 by 133 feet. The filtering medium consists of two layers of broken stone varying from ¾ to ⅛ inch in size, 4 inches of coarse sand and 2 feet 4 inches of fine sand ($\frac{1}{80}$ to $\frac{1}{40}$ inch). The depth of water varies from 3 feet 10 inches to 4 feet 9 inches. The filtering layer consists of 2 distinct portions, both of which affect the rate of flow: (1) The sedimentary skin which forms on surface of sand, and (2) the gelatinous layer which consists of the top layer of sand. The former sometimes forms as a feltlike skin which, on drying, curls up in sheets about 5 feet square. There is normally no growth of algae in this skin; but on occasions when depth of water has been reduced for several days, rapid growth has occurred. The gelatinous layer is usually 1½ inches deep below sand surface and sometimes extends to a depth of 9 inches. When filter first becomes clogged, it can be restored for a time by simply removing the sedimentary layer. This may sometimes be repeated several times before removing and washing the surface sand. When the depth of filtering sand is reduced to 15 inches by removing surface layer for washing, the bed is made up to original depth with clean sand. To prevent penetration of finely divided organic matter into the sand of a newly washed filter, water is allowed to stand on surface for 24 hours to permit suspended matter to settle, and for first three days the rate of filtration is gradually increased from ½ inch to 4 inches, vertical, per 24 hours.

During the hot weather, hydrogen sulphide is produced in the filters. When the filters are stopped, a black layer about 2 inches thick is found at the bottom of the fine sand, immediately above the coarse sand; and occasionally a similar layer immediately below the surface of the fine sand. This is probably iron sulphide, as the sand contains iron. Liberation of the hydrogen sulphide through the sand of the filter causes formation of craterlike holes in the sand surface, which, of course, interfere with the efficiency. The presence of the hydrogen sulphide in the filtered water prevents satisfactory chlorination.

After studying the situation, the author recommended that the slow sand filters be converted into rapid sand filters by emptying and using filters Nos. 1–14 as preliminary settling basins, Nos. 15 and 17 as coagulation basins for alum treatment, and dividing No. 16 into 14 rapid sand filters to be operated at a rate of 100 vertical inches per hour. This would give a net capacity of 20 m. g. d., to supply a consumption of 17 m. g. d.

In spite of the recommendation, the corporation decided to extend the slow sand filters, but the Government refused to assist financially. As a result no action has been taken, and there is no propsect of any improvement in the near future.

Sludge Thickening and Discharge. A. W. Bull and G. M. Darby. *Water Works*, vol. 67, No. 2, February, 1928, p. 76. (Abstract by H. B. Hommon.)

In some laboratory tests it was found that the slow stirring of dilute suspensions of mud in water caused a concentration of sludge in 10 hours that was not equalled in 47 to 75 hours of quiescent settling. Tests were made with an experimental Dorr clarifier in which three methods of discharging sludge were tried: (1) Discharge through a swivelled pipe which could be readily swung up or down to control the discharge head; (2) combinations of the swivel pipe and different sized orifices; (3) by the use of a diaphragm pump.

The conclusions drawn from the tests were: (1) The clarifier demonstrated its ability to thicken river mud and to discharge the sludge with a water loss of less than 1 per cent; (2) for the handling of this type of sludge, the piping should be free from shoulders or any obstructions, flange joints being recommended; (3) either orifice or swivel discharge may be used, but either will require careful manipulation and fairly close attention; (4) the diaphragm pump handled and controlled the sludge discharge without any difficulty, and could consistently remove sludge of a greater density than could be continuously discharged through an orifice or through the swivel pipe.

Value of Preliminary Sedimentation in Water Purification. Frank Bachmann. Proceedings of Ninth Texas Water Works Short School, January, 1927, pp. 173–180. (Abstract by H. D. Cashmore.)

An article that should be of particular interest to those operators of water purification plants whose water is taken from rivers of the Mississippi drainage basin where wide fluctuations of turbidity is experienced.

The advantages of preliminary sedimentation in the treatment of turbid waters are as follows:

1. The removal of the bulk of the turbidity, thereby reducing the load on the coagulation basins and consequently the cost of cleaning these basins.

2. Presettling gives a water low in turbidity, which (*a*) results in smoother plant operation, (*b*) reduces materially the cost of chemicals for coagulation and softening, (*c*) reduces cost of water wasted with sludge as this water has not been treated with chemicals.

An interesting discussion of the above advantages is given, with several charts and tables to illustrate the points brought to light.

Figure A is a graph showing the reduction of turbidity obtained with a short period of sedimentation at several cities on the Mississippi, Missouri, and Arkansas Rivers. Figure B shows the form in which the mass of data available at nearly all filtration plants regarding turbidity and alkalinity and lime and alum consumption can be represented graphically. In Figure C some interesting data dealing with lime consumption for different turbidities for deduction of bicarbonate alkalinity are shown in graphs.

Two tables showing the operating results at Little Rock, Ark., and St. Louis, Mo., where presedimentation is used, are given to show what results can be obtained. The last table gives a comparison between the yearly operating costs at Waco, Tex., for the years 1918–19 and 1919–20, which shows the saving made by the installation of a sedimentation basin.

DEATHS DURING WEEK ENDED MAY 19, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended May 19, 1928, and corresponding week of 1927. (From the Weekly Health Index, May 23, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended May 19, 1928	Corresponding week, 1927
Policies in force	71, 199, 412	67, 703, 113
Number of death claims	15, 244	13, 565
Death claims per 1,000 policies in force, annual rate	11. 2	10. 4

Deaths from all causes in certain large cities of the United States during the week ended May 19, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, May 23, 1928, issued by the Bureau of the Census, Department of Commerce)

[3] Deaths for week ended Friday, May 18, 1928.

[4] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31; Baltimore, 15; Birmingham, 39; Dallas, 15; Fort Worth, 14; Houston, 25; Indianapolis, 11; Kansas City, Kans., 14; Knoxville, 15; Louisville, 17; Memphis, 38; Nashville, 30; New Orleans, 26; Richmond, 32; and Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State, or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 101 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,650,000. The estimated population of the 95 cities reporting deaths is more than 30,960,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended May 12, 1928, and May 14, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
41 States	1,225	1,547	
101 cities	733	1,037	861
Measles:			
40 States	18,357	12,997	
101 cities	8,330	3,587	
Poliomyelitis:			
41 States	32	20	
Scarlet fever:			
41 States	3,764	4,560	
101 cities	1,530	2,022	1,228
Smallpox:			
41 States	860	695	
101 cities	107	125	116
Typhoid fever:			
41 States	207	324	
101 cities	48	47	42
Deaths reported			
Influenza and pneumonia.			
95 cities	1,439	793	
Smallpox:			
95 cities	0	0

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended May 12, 1928, compared with those for a like period ended May 14, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1928 and 1927, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,657,000 in 1928 and 31,050,000 in 1927. The 95 cities reporting deaths had nearly 30,961,000 estimated population in 1928 and nearly 30,370,000 in 1927. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, April 8 to May 12, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

THE FAR EAST

Reports for the weeks ended April 28 and May 5, 1928.—The following reports for the weeks ended April 28 and May 5, 1928, were transmitted by the Eastern Bureau of the Health Section of the Secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Week ended April 28, 1928

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Egypt.—Suez.
Aden Protectorate.—Aden.
India.—Bassein, Bombay, Rangoon.
Siam.—Bangkok.

CHOLERA

India.—Bassein, Calcutta, Madras, Moulmein, Rangoon, Tuticorin.
French India.—Pondicherry.
Straits Settlements.—Singapore.
Siam.—Bangkok.
French Indo-China.—Saigon.

SMALLPOX

Iraq.—Basra.
India.—Bombay, Calcutta, Madras, Moulmein, Negapatam, Rangoon, Tuticorin.
French India.—Pondicherry.
China.—Shanghai, Hong Kong.
Japan.—Osaka, Shimonoseki.
Kwantung.—Dairen.
South Manchuria.—Changchun.
Manchuria.—Mukden.

Returns for the week ended April 28 were not received from the following ports:

Aden Protectorate.—Perim.
Dutch East Indies.—Belawan-Deli, Samarinda, Padang.
Union of Soviet Socialist Republics.—Vladivostok.

Week ended May 5, 1928

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Aden Protectorate.—Aden.
India.—Bassein, Bombay, Rangoon.
Dutch East Indies.—Surabaya.
China.—Hong Kong.

CHOLERA

India.—Bassein, Bombay, Calcutta, Madras, Moulmein, Negapatam, Rangoon, Tuticorin.
Siam.—Bangkok.
French Indo-China.—Haiphong, Saigon.

SMALLPOX

India.—Bassein, Bombay, Calcutta, Madras, Moulmein, Negapatam, Rangoon.
French India.—Pondicherry.
Dutch East Indies.—Banjermasin, Belawan-Deli.
China.—Shanghai, Hong Kong.
Japan.—Osaka, Shimonoseki
Kwantung.—Dairen.
South Manchuria.—Changchun.
Manchuria.—Antung.

Returns for the week ended May 5 were not received from Vladivostok, Union of Soviet Socialist Republics.

ANGOLA

Communicable diseases—February, 1928.—During the month of February, 1928, communicable diseases were reported in Angola as follows:

Disease	Coast district	Land frontier	Interior	Total
Ancylostomiasis	6	43		49
Beriberi	1			1
Bilharzia	21	3	29	53
Chicken pox	3	2	2	7

Venereal diseases	170	150	33	353
Whooping cough	11		2	13
Yaws	211	50	22	283

Population: 4,119,000.

ARABIA

Aden—Plague conditions—Summary of prevalence to April 14, 1928.—Under date of April 16, 1928, it was stated that epidemic plague at Aden showed some abatement in the Crater, but that a new focus had developed in the Maala district, in the vicinity of the wharves. The total number of cases to April 14, 1928, was stated to be 1,387, with 1,006 deaths.

CANADA

Provinces—Communicable diseases—Week ended May 5, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from seven Provinces of Canada for the week ended May 4, 1928, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever			1	2				3
Influenza	18			11				29
Smallpox				8	7	12	2	[illegible]
Typhoid fever		2	12	18	1	1	4	38

Quebec—Communicable diseases—Week ended May 12, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended May 12, 1928, as follows:

Disease	Cases	Disease	Cases
Chicken pox	40	Scarlet fever	94
Diphtheria	42	Smallpox	13
German measles	21	Tuberculosis	68
Influenza	5	Typhoid fever	19
Measles	227	Whooping cough	6

Vital statistics—Quebec Province—March, 1928.—Births and deaths in the Province of Quebec for the month of March, 1928, were reported as follows:

Estimated population	2,650,400	Deaths from—Continued.	
Births	6,999	Heart disease	325
Birth rate per 1,000 population	31.2	Influenza	120
Deaths	3,131	Measles	27
Death rate per 1,000 population	13.9	Pneumonia	330
Deaths under 1 year	840	Scarlet fever	12
Infant mortality rate	120.0	Smallpox	1
Deaths from—		Syphilis	6
Cancer	178	Tuberculosis (pulmonary)	203
Cerebrospinal meningitis	12	Tuberculosis (all other causes)	53
Diphtheria	33	Typhoid fever	15
Diabetes	20	Violence	63
Diarrhea	117	Whooping cough	41

ESTONIA

Communicable diseases—March, 1928.—During the month of March, 1928, communicable diseases were reported in the Republic of Estonia as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	14	Scarlet fever	420
Diphtheria	40	Tuberculosis	212
Measles	76	Typhoid fever	20

Population 1,114,630.

GREAT BRITAIN

Castleford—Epidemic smallpox.—Under date of April 28, 1928, epidemic smallpox, with 93 cases, was reported at Castleford, England, a manufacturing and mining town of 25,000 inhabitants situated in the vicinity of Leeds. The first case was stated to have occurred February 20, 1928.

HAITI

Meningococcus meningitis.—A report dated May 9, 1928, states that the epidemic of meningococcus meningitis in the northern part of the island of Haiti had subsided. The disease was confined to mountain districts of the Department of the North, and did not reach epidemic proportions in any city or town. The fatality rate was said to be 12½ per cent among the treated cases. On May 5, 1928, 57 cases remained under treatment, all but 5 of which were convalescent.

ITALY

Communicable diseases—February 13–26, 1928.—During the two weeks ended February 26, 1928, communicable diseases were reported in the Kingdom of Italy as follows:

Disease	Feb. 13–19, 1928		Feb. 20–26, 1928	
	Cases	Communes affected	Cases	Communes affected
Anthrax	13	13	21	20
Cerebrospinal meningitis	6	6	5	[illegible]
Chicken pox	336	126	370	[illegible]
Diphtheria	496	271	439	[illegible]
Dysentery	1	1	1	1
Lethargic encephalitis	6	7	9	9
Measles	2, 339	350	2, 896	[illegible]
Poliomyelitis	9	9	6	6
Scarlet fever	397	170	327	187
Smallpox	2	2	2	[illegible]
Typhoid fever	395	211	321	178

LATVIA

Communicable diseases—March, 1928.—During the month of March, 1928, communicable diseases were reported in the Republic of Latvia as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	15	Puerperal fever	[illegible]
Diphtheria	63	Scabies	[illegible]
Erysipelas	18	Scarlet fever	237
Influenza	49	Tetanus	2
Leprosy	2	Trachoma	40
Malaria	1	Typhoid fever	[illegible]
Measles	822	Typhus fever	[illegible]
Mumps	22	Whooping cough	[illegible]

Population, estimated: 1,950.

UNION OF SOUTH AFRICA

Cape Province—Typhus fever—Week ended April 7, 1928.—During the week ended April 7, 1928, fresh outbreaks of typhus fever were reported in the Glen Gray and Xalanga districts, Cape Province, Union of South Africa.

URUGUAY

Montevideo—Communicable diseases—January, 1928.—During the month of January, 1928, communicable diseases were reported at Montevideo, Uruguay, as follows:

Disease	Cases	Disease	Cases
Diphtheria	34	Scarlet fever	21
Leprosy	1	Tuberculosis	159
Measles	[illegible]	Typhoid fever	10

Population: [illegible].

Mortality from communicable diseases.—During the period under report 7 deaths from measles, 1 death from scarlet fever, and 104 deaths from tuberculosis were reported at Montevideo.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

TREASURY DEPARTMENT

PUBLIC HEALTH REPORTS

ISSUED WEEKLY

BY THE UNITED STATES
PUBLIC HEALTH SERVICE

VOLUME 43 :: :: NUMBER 23

JUNE 8 - - - 1928

SPECIAL ARTICLE

The Blacktongue-Preventive Action of 16 Foodstuffs, with Reference to Identity of Blacktongue and Pellagra

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON
1928

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen R. C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

VOL. 43 JUNE 8, 1928 NO. 23

A STUDY OF THE BLACKTONGUE-PREVENTIVE ACTION OF 16 FOODSTUFFS, WITH SPECIAL REFERENCE TO THE IDENTITY OF BLACKTONGUE OF DOGS AND PELLAGRA OF MAN

By JOSEPH GOLDBERGER and G. A. WHEELER, *Surgeons*, and R. D. LILLIE and L. M. ROGERS, *Passed Assistant Surgeons, United States Public Health Service*

CONTENTS

Some of the results of our study of the problem of an experimental animal for pellagra were briefly summarized in a communication published two years ago (1), and have been presented in detail in two recent publications. In the first of these Goldberger and Wheeler (2) reported the production in the dog, by feeding pellagra-producing diets, of a pathological condition considered by them to be identical with the spontaneously occurring canine disease known to American veterinarians as blacktongue.[1] The clinical resemblance of this canine disease to pellagra in man was discussed and was considered so striking as to be, in itself, practically conclusive of the identity of these two conditions. In harmony with and supporting this view was also the suggestion of a common etiology indicated by the successful production of the canine disease by feeding with pellagra-producing diets. In the second communication, Goldberger, Wheeler, Lillie, and Rogers (3) reported a series of feeding experiments with yeast, from the results of which they concluded that experimental blacktongue is due to a deficiency in diet that is capable of being corrected by something present in abundance in yeast. This demonstration of the presence of the blacktongue preventive in yeast, a substance in which the pellagra preventive (factor P-P) was also known to be present in abundance (4), was considered to increase somewhat the probability that blacktongue and pellagra are fundamentally identical

[1] Synonyms: Stuttgart dog epizootic; typhus der Hunde (dog typhoid); typhus of dogs; gastro-enteritis hemorrhagica; southern canine plague, sore mouth of dogs.

conditions. In this connection it is of interest to note that Denton (5), in a study of the tissue changes in experimental blacktongue, has found that the lesions of the skin, mouth, pharynx, esophagus, and colon in the canine disease are very similar to those in pellagra, and that histologically the lesions in experimental blacktongue duplicate those in pellagra.

In the body of this report reference will be made to differences between certain of the results of our study and those of an apparently similar study by Underhill and Mendel (6). The divergence in our results is of interest, since we have heretofore considered it highly probable that the pathological condition experimentally induced in the dog by Chittenden and Underhill and studied by Underhill and Mendel was identical with the experimental condition studied and identified by us as blacktongue (2). The extensive report of their work (7) which has just come to our attention presents some clinical details which not only seem in themselves significant of a difference in the two pathological conditions, but also suggest that we had heretofore, perhaps, underestimated the significance of certain other clinical differences. Thus we find in this report that a "troublesome skin rash" appears to have been common in the condition with which Underhill and Mendel have worked. We have encountered none such in our dogs. On the other hand, while we have observed a pellagra-like dermatitis of the scrotum in some 40 to 50 per cent of attacks in our male dogs, there is no mention of the occurrence of such an eruption in the condition studied by Underhill and Mendel. Again, in the condition studied by us—namely, blacktongue—there is a definitely marked febrile stage which does not seem to occur in the Chittenden-Underhill syndrome studied by Underhill and Mendel; for they nowhere make mention of it, not even in their full report. These clinical differences seem to us of such importance that, in spite of the striking clinical similarity in certain other respects, doubt now arises as to the identity of the Chittenden-Underhill "pellagra-like" syndrome. Until this doubt is definitely resolved one way or another, it would seem premature to discuss, and we therefore do not attempt to discuss, the differences between the results reported by Underhill and Mendel and those recorded by ourselves in the present and in a preceding communication (3).

In the present communication we present some further results of our study of experimental blacktongue. These results deal with the blacktongue preventive potency of certain selected foodstuffs, 16 in number, with special reference to the relation of experimental blacktongue of dogs to pellagra of man.

METHODS AND CRITERIA

The general methods of caring for and feeding our experimental animals have already been described (2) (3). We may recall, however, that the experimental diets were, as a rule, freshly prepared each day. The daily allowance of food was, in general, intended to be no more than enough for the maintenance of normal body weight. An exception was made in the case of young growing animals, to which more than this allowance was offered. It may be recalled, too, that it has been our practice to use our dogs repeatedly with or without intermediate periods of stock feeding as might be demanded by the purpose of the experiment. In stock feeding, a definite food mixture has been used, principally our diet No. 156, the composition and evidence of the adequacy of which have been given in a preceding communication (2).

In testing for the blacktongue preventive we have employed both the curative and the preventive procedure, singly or in combination. Since, as we have in a preceding communication (2), already indicated the clinical course of experimental blacktongue, especially in the invasional stage, may normally be of an intermittent or relapsing character, we attach no significance to a seemingly favorable therapeutic result in cases in which the treatment is begun early unless confirmed by the results of a preventive test. On the other hand, consistently unfavorable results of treatment under such favoring circumstances have been considered trustworthy indications of a poverty in or lack of the blacktongue preventive, provided that the test dose has been a liberal one. Our experience with experimental blacktongue has led us to consider the rise in temperature which occurs in the advanced stage of the disease as a mark of gravity (2). Only very exceptionally does the attack normally remit after this temperature rise has taken place. We have, therefore, been disposed to consider clinical recovery from the attack (that is, disappearance of all manifestations of the disease with recovery of appetite) following treatment begun at this advanced grave stage as significant, but have, nevertheless, always required confirmation by the preventive test before drawing final conclusions with respect to the presence of the preventive in the substance thus found to be active. Isolated cases of the apparent failure of treatment under these unfavorable circumstances have been considered as without significance.

In testing the individual foodstuffs, one, or exceptionally both, of two types of test diet have been employed. In the first the components other than the foodstuff under investigation are believed to have contributed none or but an insignificant amount of the blacktongue preventive; in the second, some, at least, of the basic components may have contributed or probably did contribute a substantial quota of the preventive. This difference in character of

basic diet should be kept in mind in evaluating and comparing the indications of preventive potency, since the results yielded by the former may probably be considered as due virtually entirely to the action of the foodstuff tested, whereas those of the latter must be considered as a summation effect due to the combined action of the basic components and of the test foodstuff.

So far as our data permit, an appraisal has been made of the blacktongue preventive potency of each foodstuff. In view of the lack of a better practicable standard for such purpose, our appraisal is simply a judgment, in broad terms, of the preventive adequacy of such a quantity as, according to conventional practice, represents the daily allowance for an average adult human male.

The experimental disease in the dog and its diagnosis have been described in a preceding report (2); we need recall only that the earliest distinctive buccal signs are a vivid red injection of the mucosa of the floor of the mouth or a peculiar reddening of the mucosa of the upper lip in the form of bilaterally symmetrical patches, or of both. We have considered the first appearance of these mouth lesions as marking the beginning of the attack of blacktongue. We have conformed to this rule in all cases, even in those relatively few instances in which the pellagralike dermatitis of the scrotum appeared in advance of the mouth lesions. Thus marked, the beginning of the experimental disease, when this is induced by feeding our basic diet No. 123 (or certain of its modifications, namely diets No. 209, No. 195, and No. 268), is only very exceptionally delayed beyond about 60 days after the beginning of the feeding (2). We have therefore been inclined to consider a very notable prolongation of this period, particularly when manifested in more than one of a group of test animals, as significant of the presence in the test diet of the blacktongue preventive in an amount that is somewhat larger than that presumably contained in our standard basic diet.[1] Since other factors, not yet understood, such, for instance, as self-imposed starvation or semistarvation and other possibly coexisting deficiencies or maladjustments of dietary essentials, may and probably do influence the duration of what for convenience may be designated as the deprivation period, we have tried to exercise due caution in the interpretation of such indications.

[1] Our basic experimental diets of the type exemplified by our diet No. 123 (Table 1) contain, we judge, a small amount of the blacktongue preventive derived from its natural-food components, principally corn meal and cowpeas. We have the impression that the "synthetic" type of diet of purified foodstuffs which, presumably, is entirely free of the blacktongue preventive, is not as satisfactory an experimental diet, principally because of a more unfavorable effect on appetite leading to earlier and more marked self-imposed starvation or semistarvation.

MAIZE

The idea that the maize in the diet is in some way concerned in the causation of pellagra has, as is well known, been entertained by students of that disease almost from the time of its first recognition. It seems to have arisen in part, at least, because maize constituted a very large part of the diet of the populations among whom, in the Old World, the disease was endemic. In the United States, maize also is a conspicuous element in the diet of the population in the area where the disease is most prevalent. Both in the Old and in the New World, therefore, maize is more or less prominently associated with the occurrence of pellagra. While the extreme position of certain zeists that there is no pellagra without maize is now no longer tenable, the association is no doubt very common. One is justified in concluding, therefore, that maize is very poor in or lacks the pellagra preventive.

In constructing our experimental diets, based as they are on diets found in association with the occurrence of pellagra, maize was from the first included as a conspicuous element. The basic diet most frequently used by us for the experimental production of blacktongue (diet No. 123, shown in Table 1) contains 400 grams of maize meal per 2,400 calorie ration. This is a large amount of cereal, constituting as it does two-thirds of the weight of the dry ingredients of the diet. Notwithstanding this, however, as has in a preceding communication (3) already been set forth, dogs fed this diet (including certain of its modifications) have developed blacktongue within a period which only exceptionally exceeded a duration of about 60 days. This would indicate that, as measured by the requirements of the dog, maize contains little if any of the blacktongue preventive. Incidentally, it may be noted that cornstarch would also appear to be very poor or lacking in the blacktongue preventive since, as previously reported (3), two dogs fed a diet (No. 281) containing 366 grams of cornstarch per 2,400-calorie portion promptly developed the disease.

The maize meal used in our basic diet No. 123 (including its modifications) does not, however, represent quite the whole kernel, since a small part of the bran is removed by sifting as if for human consumption. It seemed desirable, therefore, to test a meal from which nothing had been taken away. But as it did not seem to us probable that the difference in the meal represented by the small amount of bran removed in sifting would of itself appreciably influence the result of feeding, and as we wished, if possible, to determine whether the maize kernel contains an appreciable amount of the blacktongue preventive, it was determined to work with a diet containing as large an amount of whole meal as possible and yet one that so far as could then be judged was adequate for maintenance in all other respects. With these considerations in mind we carried out Experiment 1.

EXPERIMENT 1

This was a test of the blacktongue preventive action of whole white maize meal which was incorporated in test diets No. 149 and No. 149A. (Table 2.) These diets, which are identical except that the butterfat of one is quantitatively replaced by cod-liver oil in the other, are a slight modification of a maize diet studied by McCollum, Simmonds, and Pitz (8), and by them considered complete for normal growth of the rat to normal adult size, and for that reason selected by us for this study. Each contains 450 grams of whole-maize meal in a ration of slightly less than 2,400 calories. Suitable portions of one or the other of these diets were offered daily to each of seven test animals, dogs 29, 40, 52, 54, 57, 65, and 73. One of these dogs served during two separate periods, so that eight tests in all are to be considered. The significant details relating to each of the test animals are presented in the following:

Dog 29.—Male Acquired May 9, 1923, between which date and January 11, 1924, served in a number of experiments and suffered four attacks of blacktongue, the latest of which began January 7, 1924. On a miscellaneous stock diet from January 11 to February 5, 1924.

February 5, 1924: In good condition; weighs 11.1 kilograms; begins test diet No. 149. (Table 2.)

On February 17, 1924, at the end of a period of 12 days, presented the first signs of an attack of blacktongue, an injection of the floor of the mouth. Further history not relevant.

Dog 40.—Male. Whelped in the laboratory June 26, 1923, and reared on a stock diet. Up to February 20, 1924, served in a number of experiments and suffered two attacks of blacktongue, the later one of which began February 19, 1924. On a stock diet for reconditioning from February 20 to March 11, 1924.

March 11, 1924: In good condition; weighs 9.2 kilograms; begins diet No. 149.

On April 23, 1924, at the end of a period of 43 days, presented the first signs of an attack of blacktongue, an injection of the floor of the mouth. Weight was 11 kilograms. Further history not relevant.

Dog 52.—Bitch. Acquired September 25, 1923. Up to February 20, 1924, served in a number of experiments and suffered two attacks of blacktongue, the later one of which began February 18, 1924. On a stock diet for reconditioning from February 20 to March 11, 1924.

March 11, 1924: In good condition; weighs 9.7 kilograms; begins test diet No. 149.

On July 31, 1924, at the end of a period of 142 days, presented the first signs of an attack of blacktongue, an injection of the floor of the mouth. Weighs 10 kilograms. Further history not relevant.

Dog 54.—Bitch. Acquired September 25, 1923. Up to January 11, 1924, served in a number of experiments and suffered an attack of blacktongue which began November 28, 1923. On reconditioning diets from January 11 to March 25, 1924.

March 25, 1924: In good condition; weighs 8.1 kilograms; begins test diet No. 149A. (Table 2.)

On June 5, 1924, at the end of a period of 72 days, presented the first signs of an attack of blacktongue, an injection of the floor of the mouth and a slight reddening of the mucosa of the upper lip on each side. Weighs 8 kilograms. Further history not relevant.

Dog 57.—Male. Acquired September 25, 1923. Up to January 15, 1924, served in a number of experiments and suffered two attacks of blacktongue, the latter of which began December 13, 1923. From January 15 to February 5, 1924, on a miscellaneous stock diet for reconditioning.

February 5, 1924: In good condition; weighs 9.7 kilograms; begins test diet No. 149.

On February 23, 1924, at the end of a period of 18 days, presented the first signs of blacktongue, an injection of the floor of the mouth, of the mucosa of the cheeks, and of the anterior faucial pillars. Weighs 10 kilograms. Begins reconditioning diet.

February 25, 1924: Redness of mucosa of the floor and cheeks is less pronounced.

February 26, 1924: Redness has practically completely faded. Weighs 9.9 kilograms.

March 25, 1924: In good condition; weighs 10.1 kilograms; begins test diet No. 149A.

On April 11, at the end of a period of 17 days, presented the beginning signs of an attack of blacktongue, an injection of the floor of the mouth. Further history not relevant.

Dog 65.—Bitch. Acquired January 28, 1924. Kept on a miscellaneous stock diet to February 5, 1924.

February 5, 1924: In good condition; weights 6.7 kilograms; begins test diet No. 149.

April 22: Weighs 7.7 kilograms.

On April 27, 1924, at the end of a period of 77 days, presented the first signs of an attack of blacktongue, a reddening of the mucosa of the floor of the mouth. Further history not relevant.

Dog 73.—Bitch. Acquired March 19, 1924. On stock diet up to April 1, 1924.

April 1, 1924: In good condition; weighs 7.7 kilograms; begins test diet No. 149A.

July 8, 1924: Weighs 10.2 kilograms.

On July 12, 1924, or 102 days after beginning the test, this animal presented an injection of the mucosa of the floor of the mouth suggestive of a beginning attack of blacktongue. Two days later this was no longer perceptible, nor was there any reappearance of signs of blacktongue during a further period of observation of 38 days which ended August 19, 1924, on which date this experiment was discontinued.

Results and conclusions.—Six of the seven dogs developed blacktongue in from 12 to 142 days after beginning the test. The seventh (dog 73) presented evanescent evidence very suggestive but not conclusive of blacktongue at the end of a period of 102 days. The observation of this animal was discontinued at the end of 140 days, so that the possibility is not excluded that a definite attack of blacktongue would have developed had the observation period been longer. One of the test animals (dog 57) served during two separate periods and developed an attack of blacktongue in each. Thus the six animals in which definite evidence of blacktongue developed experienced, in all, seven attacks. Six of these appeared at the end of periods of not over 77 days in duration, and the seventh (dog 52) at the end of a period of 142 days.

The unusually long interval before the development of the attack in one and the occurrence of but evanescent indications of an attack in another of the experimental animals, even though the observa-

tion period in the latter was but 140 days, suggest, by contrast with our experience with basic diet No. 123 (including certain of its modifications (3)), that the test diets under consideration may have possessed slight preventive properties. The difference is not very notable and, such as it is, can not be attributed, altogether at least, to the character and increased quantity of the maize, since one of the test diets (No. 149), unlike our standard basic diet (No. 123), contained some butter, which, as will presently be seen, while a poor source is not entirely devoid of the preventive factor, a fact that was not fully appreciated when this experiment was planned. This experiment is therefore not conclusive. Notwithstanding this, however, the evidence quite clearly indicates that, at best, this cereal is a very poor source of the blacktongue preventive.

Recalling the indications of its poverty in or lack of the pellagra preventive it would appear that maize, if it contains any, is a poor source of the preventive for both blacktongue and pellagra.

WHEAT

The important place among the cereals held by wheat and a desire to compare it with maize led us to test its blacktongue preventive potency. The following experiment was accordingly carried out.

EXPERIMENT 2

For the present purpose, wheat ground in this laboratory into a meal was, without sifting, incorporated in a diet, No. 128, the composition of which is shown in Table 3. This, as may be seen by reference to Table 1, is essentially diet No. 123, the maize meal of which has been quantitatively replaced by the ground wheat, of which there are, therefore, 400 grams in each 2,400-calorie portion. Some of this diet was daily offered to each of eight test animals—dogs 5, 9, 13, 14, 29, 38, 44, and 47. The significant details relating to each are briefly as follows:

Dog 5.—Bitch. Acquired November 8, 1921. Has served in a number of experiments and has suffered two attacks of blacktongue, the later one of which began August 28, 1923. On stock diet from September 8, 1923, to January 29, 1924 Whelped a litter of seven pups November 25, 1923, six of which survived and were weaned in good condition January 17, 1924.

January 29, 1924: In good condition; begins diet No. 128. (Table 3.)

On August 2, 1924, at the end of a period of 186 days, presented the first signs of blacktongue, a reddening of the mucosa of the cheeks. To this there was added on August 3 a reddening of the mucosa of the floor of the mouth and of that of the upper lip on the left side. Further history is not relevant.

Dog 9.—Male. Acquired April 1, 1923. Has served in a number of experiments and has suffered four attacks of blacktongue of which the latest began February 12, 1924. On stock diet from February 13, to March 11, 1924.

March 11, 1924: In good condition; begins diet No. 128.

On July 31, 1924, at the end of a period of 142 days, presented the first signs of an attack of blacktongue, a reddened patch on the mucosa of the upper lip, in the region of the canines, on each side, and a slight reddening of the mucosa of the floor of the mouth. Further history is not relevant.

Dog 13.—Male. Acquired April 7, 1923. Up to November 28, 1923, served in several experiments and suffered three attacks of blacktongue, of which the latest began November 24, 1923. On a reconditioning diet from November 28 to December 11, 1923.

December 11, 1923: In good condition; begins diet No. 128.

On February 20, 1924, or at the end of a period of 71 days, presented an injection of the floor of the mouth which was slightly more pronounced the next day, February 21. This reddening then persisted without notable change for some 48 hours, then rapidly faded so that the mouth was normal on February 25.

On July 11, or at the end of an additional period of 142 days, presented renewed signs of blacktongue, an erythematous patch on the mucosa of the upper lip on each side in the region of the canines and a slight reddening of the floor of the mouth. Further history not relevant.

Dog 14.—Male. Acquired April 7, 1923. Up to November 28, 1923, served in several experiments and suffered four attacks of blacktongue, of which the latest began October 30, 1923. On a reconditioning diet from November 28 to December 11, 1923.

December 11, 1923: In good condition; begins diet No. 128.

On June 24, 1924, or at the end of a period of 196 days, presented the first signs of an attack of blacktongue, a slight reddening of the mucosa of the floor of the mouth. Further history not relevant.

Dog 29.—Male. Acquired May 9, 1923. Up to November 27, 1923, served in several experiments and suffered three attacks of blacktongue, of which the latest began October 18, 1923. On a reconditioning diet from November 27 to December 11, 1923.

December 11, 1923: In good condition; begins diet No. 128.

On January 7, 1924, at the end of a period of 27 days, presented the first signs of an attack of blacktongue, a reddening of the mucosa of the floor of the mouth.

Dog 38.—Male. Whelped in the laboratory June 26, 1923. Up to February 20, 1924, served in several experiments and suffered two attacks of blacktongue, the second one of which began February 14, 1924. On a reconditioning diet from February 20 to March 11, 1924.

March 11, 1924: In good condition; begins diet No. 128.

On June 24, 1924, at the end of a period of 105 days, presented the first signs of an attack of blacktongue, a reddening of the floor of the mouth. Further history not relevant.

Dog 44.—Male. Whelped in the laboratory June 26, 1923. Up to December 27, 1923, served in one experiment and suffered an attack of blacktongue which began October 28, 1923. On a reconditioning diet from December 27, 1923, to January 29, 1924.

January 29, 1924: In good condition; begins diet No. 128.

On August 13, 1924, at the end of a period of 197 days, presented the first signs of an attack of blacktongue, reddened patches on the mucosa of the upper lip on each side. Further history not relevant.

Dog 47.—Male. Acquired August 18, 1923. Up to November 28, 1923, served in an experiment and suffered an attack of blacktongue, which began September 28, 1923. On a reconditioning diet from November 27 to December 20, 1923.

December 20, 1923: In good condition; begins diet No. 128.

On January 7, 1924, at the end of a period of 18 days, presented the first signs of an attack of blacktongue, a reddening of the floor of the mouth. Further history not relevant.

Results and conclusions.—As is evident, all eight of the test animals developed blacktongue. It is noteworthy, however, that in but two of the dogs did the attack have its onset at the end of periods shorter than 71 days. In five of the eight animals the first signs of the attack made their appearance at the end of periods varying between 105 and 197 days—that is, after periods very definitely longer than is the rule in the case of dogs fed diet No. 123. This delay in the development of the disease would appear to indicate that diet No. 128 had exercised appreciable but incomplete blacktongue preventive action and, therefore, that whole wheat contains the blacktongue preventive, but in small amount. Compared with the result of the experiment with whole maize, the outcome of the test of whole wheat suggests that this is probably a slightly better source of the blacktongue preventive than is the maize.

WHEAT GERM

While the preceding experiment with whole wheat was under way, tests were made of the blacktongue-producing potency of a number of diets in which were included varying amounts of commercial wheat germ as a source of "vitamin B." The results of one of these tests which happened to be with a diet that included an unusually large quantity of the wheat germ, suggested rather strongly that this germ might possess definite blacktongue-preventive action. This led us to carry out the following experiment:

EXPERIMENT 3

This was a test of the blacktongue-preventive action of ether-extracted wheat germ. The wheat germ was a commercial product from which we had extracted the fat by percolation with ether (U. S. P.) at air temperature.[1] It was incorporated in a diet, No. 197, the composition of which is shown in Table 4. As may be seen, each 2,400 calorie portion contains 180 grams of the extracted germ. It may be noted, too, that it contains a considerable amount of cornstarch; notably less, however, as was noted in the preceding section in connection with maize, than has been found to be lacking in appreciable blacktongue-preventive action. This diet is somewhat similar to our basic diet No. 123 (Table 1), from which it differs notably, however, in that the wheat germ and the starch of the former completely replace the corn meal and cowpeas of the latter. Suitable portions of the diet were daily offered to each of nine test-

[1] Various batches of this ether-extracted wheat germ were found by Assistant Chemist C. G. Remsburg, in the Division of Chemistry of the Hygienic Laboratory, to contain from 0.02 to 0.34 per cent of "ether extract."

animals, dogs 54, 61, 65, 70, 71, 78, 86, 87, and 88. The significant details relating to each are presented in the following:

Dog. 54—Bitch. Acquired September 25, 1923. Up to June 17, 1924, served in several experiments and suffered two attacks of blacktongue of which the second began June 5, 1924. On stock diet for reconditioning from June 17 to July 23, 1924. On an experimental diet, which included some wheat germ, from July 23, 1924, to May 26, 1925.

May 26, 1925: In good condition; begins wheat-germ diet No. 197. (Table 3.)

On September 19, 1925, at the end of 136 days, this animal presented a slight but very suggestive reddening of the mucosa of the floor of the mouth, which, however was no longer perceptible 24 hours later. No further evidence suggesting blacktongue appeared during the remainder of the period of observation, which ended May 26, 1926. In good condition at the end of one year on the wheat-germ diet.

Dog 61.—Male. Whelped in the laboratory November 4, 1923. Up to May 27, 1924, served in one experiment and suffered one attack of blacktongue, which began May 21, 1924. On reconditioning diet from May 27 to July 23, 1924. From July 23, 1924, to May 26, 1925, on an experimental diet, which included a considerable amount of wheat germ.

May 26, 1925: In good condition; begins wheat-germ diet No. 197.

On January 5, 1926, or at the end of a period of 224 days, there were noted the first signs of an attack of blacktongue, which ended in death on January 20, 1926.

Dog 65.—Bitch. Acquired January 28, 1924. Up to May 27, 1924, served in one experiment and suffered an attack of blacktongue. On stock diet for reconditioning from May 27 to July 23, 1924. On an experimental diet, which included wheat germ from July 23, 1924, to May 26, 1925.

May 26, 1925: In good condition; begins wheat-germ diet No. 197.

On February 3, 1926, at the end of 253 days, this animal presented a slight but suggestive reddening of the mucosa of the floor of the mouth and of the cheeks which, however, had completely faded 24 hours later. No further evidence suggesting blacktongue appeared during the remainder of the period of observation, which ended May 26, 1926. In good condition at the end of one year on the wheat-germ diet.

Dog 70.—Male. Whelped in the laboratory November 25, 1923. Up to May 14, 1924, served in one experiment and suffered an attack of blacktongue, which began May 13, 1924. On stock diet for reconditioning from May 14 to July 23, 1924. On an experimental diet, which included wheat germ, from July 23, 1924, to May 26, 1925.

May 26, 1925: In good condition; begins wheat-germ diet No. 197.

On September 15, 1925, or at the end of a period of 112 days, presented the first signs of an attack of blacktongue, reddened lesions on the mucosa of the upper lip opposite the canines, and an injection of the floor of the mouth. Further history not relevant.

Dog 71.—Male. Whelped in the laboratory November 25, 1923. Reared on miscellaneous stock diets. On an experimental diet, which included wheat germ, from July 23, 1924, to May 26, 1925.

May 26, 1925: In good condition; begins wheat-germ diet No. 197.

May 26, 1926: Completes one year on the wheat-germ diet in good condition; has presented no recognizable evidence of blacktongue during the year.

Dog 78.—Male. Acquired June 9, 1924. On an experimental diet which included wheat germ from July 23, 1924, to May 26, 1925.

May 26, 1925: In good condition; begins wheat-germ diet No. 197.

On August 11, 1925, at the end of a period of 77 days, presented the first signs of an attack of blacktongue, which ended in death during the night of August 22–23, 1925.

Dog 86.—Bitch. Whelped in the laboratory October 12, 1924. On stock diet to April 28, 1925. From April 28 to May 26, 1925, on an experimental diet which included wheat germ.

May 26, 1925: In good condition; begins wheat-germ diet No. 197.

On December 27, 1925, at the end of 215 days, presented a suggestive reddening of the mucosa of the floor of the mouth which gradually faded during the succeeding 48 hours. Presented no other evidence of blacktongue at any time during a further period of observation which ended May 26, 1926. In good condition at the close of the year on the wheat-germ diet.

Dog 87.—Bitch. Whelped in the laboratory October 12, 1924. On stock diet up to April 28, 1925. From April 28 to May 26, 1925, on an experimental diet which included wheat germ.

May 26, 1925: In good condition; begins wheat-germ diet No. 197.

May 26, 1926: Completes one year on the wheat-germ diet. Is in good condition. Has presented no recognizable evidence of blacktongue at any time during this feeding period.

Dog 88.—Male. Whelped in the laboratory October 12, 1924. On stock diet to April 28, 1925. From April 28 to May 26, 1925, on an experimental diet which included wheat germ.

May 26, 1925: In good condition; begins diet No. 197.

On December 18, at the end of a period of 206 days, presented the first signs of an attack of blacktongue, reddened lesions of the mucosa of the upper lip, reddening of the mucosa of the floor of the mouth and of that of the cheeks. Further history not relevant.

Results and conclusions.—From the foregoing it appears that four of the nine test animals, namely, dogs 61, 70, 78, and 88, developed definite attacks of blacktongue at the end of 224, 112, 77, and 206 days, respectively; three (dogs 54, 65, and 86) presented suggestive but fleeting evidence of blacktongue at the end of 136, 253, and 215 days, respectively; while two presented no recognizable evidence of the disease during the period of observation of one year. The notable delay in the development of two of the four definite attacks, the occurrence of but evanescent signs in three, and of no recognizable evidence whatever in two of the test animals would seem clearly to indicate that diet No. 197 had exercised definite but not fully complete blacktongue-preventive action, and, thus, that commercial wheat germ contains the blacktongue preventive. Considering quantity, and also that, so far as can be judged, the other components of the test diet (No. 197) probably contributed little or nothing to its blacktongue-preventive potency, it may be concluded that wheat germ is a relatively good, if not rich, source of the blacktongue preventive. Since wheat-germ diet No. 197 contains less than one-half as much wheat germ as diet No. 128 (Experiment 2, Table 3) contains of whole wheat, and since the protective action of the wheat-germ diet seems to have been, if anything, more marked that that of the whole-wheat diet, even with its included cowpeas, it would seem per-

missible to infer that gram for gram extracted wheat germ contains more than twice as much of the blacktongue preventive as does whole wheat.

It may here be noted that the favorable outcome of the foregoing study in the dog suggested the desirability of a similar study in human pellagra with the result elsewhere (9) already reported, that a daily supplement of 150 grams of commercial wheat germ was found effective as a preventive of the human disease. It is apparent, therefore, that commercial wheat germ contains and may be rated as a relatively good source of the preventive for both the human and the canine disease, pellagra and blacktongue.

COWPEA

The cowpea (*Vigna sinensis*) is one of the favorite legumes of our Southern States, the area in which pellagra is most prevalent. It not infrequently appears as a component of diets associated with pellagra. Its pellagra-preventive potency was studied in 1919 by Goldberger and Tanner (4), who concluded that the dry cowpea has little, if any, pellagra-preventive value. More recently Goldberger and Wheeler (9) were led to study this legume again and found that a supplement of 150 grams a day had a beneficial, delaying, but not quite a complete preventive action, and thus concluded (*a*) that the pellagra preventive is present in the cowpea, but in relatively small amount, and (*b*) that it is at least appreciably inferior in pellagra-preventive potency to the wheat germ.

Our experience with the cowpea in experimental blacktongue parallels quite closely the foregoing experience with it in the human disease, as may be seen in the following experiments:

EXPERIMENT 4

This was a test of the blacktongue-preventive action of the dried California black-eyed pea, one of the favorite varieties of the cowpea. It was incorporated in a diet, No. 286, the composition of which is shown in Table 5. As may there be seen, a 2,400-calorie portion of that diet contains 360 grams of the dried legume. Suitable portions were daily offered to each of five test animals, namely, dogs 15, 40, 52, 113, and 114. The significant details relating to each are briefly as follows:

Dog 15.—Male. Acquired April 14, 1923. Has served in several experiments and has suffered four attacks of blacktongue, the latest of which began December 25, 1924. On stock diet from December 21, 1926, to March 3, 1927.

March 3, 1927: In good condition; weighs 10.2 kilograms; begins cowpea-diet No. 286. (Table 5.)

On June 28, at the end of a period of 117 days, presented the first signs of an attack of blacktongue, a faint red patch on the mucosa of the upper lip opposite the canine teeth of each side and an injection of the floor of the mouth. The

attack slowly progressed with some remissions, and by July 12 was well marked and, besides showing distinctive buccal lesions, was characterized by a well-marked scrotal eruption. On the latter date the dog was killed with illuminating gas for histopathological study (5).

Dog 40.—Male. Whelped in the laboratory June 26, 1923. Has served in several experiments and suffered three attacks of blacktongue, of which the latest began April 23, 1924. On stock diet from December 21, 1926, to March 3, 1927.

March 3, 1927: In good condition; weighs 11.2 kilograms; begins test diet No. 286.

On July 9, at the end of a period of 98 days, presented the first buccal signs of blacktongue, a slight band of erythema on the mucosa of the upper lip of each side and an injection of the mucosa of the faucial pillars. A scrotal eruption appeared on June 28. By July 11 the mouth lesions had become very pronounced and treatment was started. Further history not relevant.

Dog 52.—Bitch. Acquired September 25, 1923. Has suffered several attacks of blacktongue, the latest of which began October 6, 1925. On stock diet from December 21, 1926, to March 3, 1927.

March 3, 1927: In good condition, weighs 10 4 kilograms; begins diet No. 286.

July 12: In good condition; weighs 10 3 kilograms; has presented no indications of blacktongue; but by reason of the development of blacktongue by some of the other dogs of this lot, the experiment is this day discontinued.

Dog 113.—Bitch. Acquired January 17, 1927. On stock diet to March 3, 1927.

March 3, 1927: In good condition; weighs 9.5 kilograms; begins diet No. 286.

July 8: Three days ago presented a very suggestive injection of the floor of the mouth and a flushing of the mucosa of the cheeks. Yesterday there was present also an ill-defined reddened band on the mucosa of the upper lip. To-day the mouth appears normal.

July 12: Food consumption has for several weeks been on a declining scale. Weighs 7.8 kilograms. Experiment is this day discontinued.

Dog 114.—Male. Acquired February 17, 1927. On stock diet to March 3, 1927.

March 3, 1927: In good condition; weighs 9.4 kilograms; begins diet No. 286.

May 10: Appetite considerably dulled and food consumption diminished during the past seven or eight days; weighs 9 kilograms.

On May 15, at the end of a period of 73 days, presented the first signs of an attack of blacktongue, an injection of the mucosa of the floor of the mouth. Further history not relevant.

Results and conclusions.—Thus, three of the test animals developed blacktongue at the end of 73, 98, and 117 days, respectively, and one (dog 113) presented very suggestive but transient indications of blacktongue at the end of 127 days. Only one (dog 52) of this lot of test animals presented no recognizable evidence of blacktongue at any time during the experimental period of 131 days. Clearly, cowpeas diet No. 286 was inadequate to prevent the development of blacktongue. The development of but transient signs of the disease in one and of none at all in another of the five dogs would, however, appear to suggest a slight delaying or protective action. That this interpretation is probably correct is indicated by the result of the following experiment with a larger ration of cowpeas.

EXPERIMENT 5

This was a further test of the blacktongue-preventive action of the dried California black-eyed pea, or cowpea. For this purpose it was incorporated in diet No. 299 (Table 6), but the quantity per 2,400-calorie portion was increased to 450 grams, or 25 per cent more than in diet No. 286 (Table 5). Suitable portions of this test diet were daily offered to each of five test animals, namely, dogs 40, 52, 113, 114, and 125. It may be noted that four of these animals (dogs 40, 52, 113, and 114) served in experiment 4 with cowpea-diet No. 286. The significant details relating to each of the animals are as follows:

Dog 40.—On stock diet for reconditioning from July 12 to August 23, 1927.

August 23, 1927: The attack of blacktongue which, as noted in the preceding experiment, began on July 9 rapidly cleared up under treatment. In good condition; weighs 12.1 kilograms; begins cowpea diet No. 299. (Table 6.)

April 10, 1928: Has presented no recognizable evidence of blacktongue since the beginning of this experiment seven and a half months ago; weighs 11.5 kilograms.

Dog 52.—On stock diet from July 12, the termination of the preceding experiment, to August 23, 1927.

August 23, 1927: In good condition; weighs 11.2 kilograms; begins test diet No. 299.

April 10, 1928: Has presented no recognizable evidence of blacktongue since the beginning of the present experiment seven and a half months ago; weighs 10.2 kilograms.

Dog 113.—On stock diet for reconditioning from July 12 to August 23, 1927.

August 23, 1927: In good condition; weighs 10.2 kilograms; begins test diet No. 299.

April 10, 1928: Food consumption has been variable; weighs 8.4 kilograms; has presented no recognizable evidence of blacktongue during the seven and one-half months since the present experiment began.

Dog 114.—On stock diet for reconditioning from June 30 to August 23, 1927, during which period all evidence of the attack of blacktongue which, as noted in connection with the preceding experiment, began May 15, completely cleared up.

August 23, 1927: In good condition; weighs 10.7 kilograms; begins test diet No. 299.

April 10, 1928: Presented transient buccal signs of blacktongue October 27–November 4; November 19–20, 1927, and February 18-19, 1928; weighs 9.8 kilograms; has presented no recognizable indications of blacktongue since the disappearance of the suggestive but evanescent lesion of the upper lip noted February 18, 1928.

Dog 125.—Bitch. Acquired May 25, 1927. On stock diet to August 23, 1927.

August 23, 1927: In good condition; weighs 7.7 kilograms; begins test diet No. 299.

April 10, 1928: Has lost some weight; weighs 6.5 kilograms; is lively and in good condition; has presented no recognizable evidence of blacktongue during the seven and one-half months since the experiment began.

Results and conclusions.—The result of this experiment with diet No. 299 presents a very distinct contrast to that of the immediately preceding one with diet No. 286. Of the five test animals on diet No. 299 only one (dog 114) developed any indications of blacktongue,

and these were mild and transient. The other four at no time during the experimental period of 7½ months (231 days) presented any recognizable evidence of the disease. Cowpea-diet No. 299 would thus seem to possess distinctly appreciable, even though not fully complete, blacktongue-preventive action. Considering the quantity of the cowpea in the test diet, we may conclude that while the cowpea (California black-eyed pea) contains the blacktongue preventive, it contains it in a relatively very small amount, probably not more than, if as much as, about one-half that contained in ether-extracted wheat germ. Recalling the experience above cited with the cowpea in human pellagra, it is evident that this dry legume, while containing it, is a poor source of the preventive for both pellagra and blacktongue.

SOY BEAN

In 1918 Goldberger and Tanner (4) studied the pellagra-preventive value of the dry soy bean and found that pellagra developed in several patients notwithstanding that they had daily ingested what was regarded as a liberal daily quantity, approximately 85 grams (3 ounces), as a supplement to the diet of the institution in which the study was made. This experience in the human disease suggested the desirability of testing the preventive action of this legume in the canine disease. This was accordingly done very early in our study of experimental blacktongue. In that test the experimental diet used (No. 110, the composition of which is shown in Table 7) was a simplified replica of the soy bean supplemented diet that had failed in the prevention of pellagra in the above-mentioned study of Goldberger and Tanner. The result of that test, using three dogs as test animals, duplicated the experience in the human disease; it failed of any indications of blacktongue-preventive action.

The quantity of soy beans included in the diet used in that experiment appearing to us as relatively large, the frank failure in blacktongue prevention seemed conclusive. But, as our investigations proceeded, we came increasingly to feel that the action of a larger quantity of this legume should be studied before final conclusions as to preventive potency could properly be drawn. Accordingly, we have quite recently tested the preventive action of the soy bean anew as shown in the following experiment:

EXPERIMENT 6

This was a test of the blacktongue-preventive action of the dried soy bean (mammoth yellow variety) when incorporated in a diet (No. 287), the composition of which is shown in Table 8. As may be seen, each 2,400-calorie portion contains 360 grams of the bean. It may be noted, too, that, like wheat-germ diet No. 197, it contained cornstarch as a conspicuous component quantitatively. Suitable

portions of this diet were daily offered to each of five test animals, namely, dogs 29, 59, 84, 112, and 116. The significant details relating to each of these animals are as follows:

Dog 29.—Male. Acquired May 10, 1923. Has suffered several attacks of blacktongue, the latest of which began April 17, 1925. On yeast-containing test diets from May 25, 1925, to March 15, 1927. On stock diet from March 15 to April 6, 1927.

April 6, 1927: In good condition, weighs 10.1 kilograms; begins soy-bean diet No. 287. (Table 8.)

May 3: Food consumption has been excellent since beginning the soy-bean diet; weighs 10 kilograms.

June 7: Appetite and food consumption were excellent up to May 16. Since that date the food consumption has been somewhat variable; weighs 9.6 kilograms.

July 5: Appetite has been increasingly variable and food consumption somewhat reduced during the past month; weighs 9.4 kilograms. Presents this morning suggestive buccal signs of blacktongue, reddened patches of mucosa of the upper lip on the left side and flushing of the mucosa of the cheeks.

July 8: Mouth lesions have faded.

July 21: A slow decline in weight continues. Presents this morning a definite reddening of the floor of the mouth and slight reddening of the mucosa of the upper lip of each side.

July 22: Mouth appears normal this morning.

August 16: Weighs 8.7 kilograms. Suggestive buccal signs of blacktongue, reddening of the floor of the mouth and of the mucosa of the cheeks again in evidence.

August 18: Mouth is well-nigh normal this morning.

September 17: Presents this morning, at end of a period of 164 days, definite beginning signs of blacktongue, a reddened bandlike patch on mucosa of the upper lip of each side, reddening of the floor of the mouth.

September 27: Buccal lesions have become quite pronounced. Weighs 7.2 kilograms. Diet changed for reconditioning. Further history not relevant.

Dog 59.—Bitch. Whelped in the laboratory November 4, 1923. Has served in one experiment but has not had blacktongue. On stock diet from March 17, 1927, to April 6, 1927.

April 6, 1927: In good condition; weighs 6 kilograms; begins soy-bean diet No. 287.

April 10, 1928: Has been on the soy-bean diet one year, during which period has at no time presented any recognizable evidence of blacktongue. Weighs 5.6 kilograms. Experiment is discontinued.

Dog 84.—Male. Acquired March 2, 1925. Has suffered an attack of blacktongue, which began April 23, 1925. On yeast-containing diets from May 23, 1925, to March 15, 1927. On stock diet from March 15, 1927, to April 6, 1927.

April 6, 1927: In good condition; weighs 10.6 kilograms; begins soy-bean test diet No. 287.

April 10, 1928: Appetite and food consumption variable but fairly good until about January 1, 1928. Since then the food consumption has become markedly reduced with coincident marked loss in weight. Weighs 6.1 kilograms; is much emaciated; mucous membranes are pale; is lively. Has presented no recognizable evidence of blacktongue at any time during the period of the experiment, now a full year in duration and terminated this day.

Dog 112.—Bitch. Acquired December 22, 1926. Except for a period of nine days—March 8–17—on stock diet to April 6, 1927.

April 6, 1927: In good condition; weighs 7.3 kilograms; begins soy-bean diet No. 287.

April 10, 1928: In good condition; weighs 8.2 kilograms. Has presented no recognizable evidence of blacktongue at any time during the experimental period of one year. Experiment is discontinued.

Dog 116.—Male. Acquired February 16, 1927. Except for the period March 9–17 on stock diet to April 6, 1927.

April 6, 1927: In good condition; weighs 7.2 kilograms; begins soy-bean diet No. 287.

April 10, 1928: In good condition; weighs 6.9 kilograms. Has presented no recognizable evidence of blacktongue during the experimental period of one year. Experiment is discontinued.

Results and conclusions.—Of the five test animals one (dog 29) developed an attack of blacktongue; the others presented no recognizable evidence of the disease at any time during the experimental period of one year. This would seem to indicate that soy-bean test diet No. 287 possessed definitely appreciable but not fully complete blacktongue-preventive action, and thus that the soy bean, in contrast with the indications of our earlier experience with a smaller quantity of this legume, contains the blacktongue preventive, but in a relatively small amount. This amount would appear to be appreciably more than in the cowpea and considerably less than in the extracted wheat germ.

The experience with the soy bean in pellagra, above cited, would seem to indicate, and was at first interpreted as indicating, a complete lack of preventive properties, just as the result of our earlier test of the soy bean in blacktongue was interpreted as an indication of a complete lack of blacktongue-preventive properties. It is clear that the interpretation with respect to the blacktongue preventive was not justified, and it must therefore be equally clear that the interpretation of the experience in pellagra must be considered inconclusive. No test of the soy bean in pellagra in more liberal amount than that in the study above cited has been made, so that it is not possible to state, on the basis of actual trial, that the soy bean actually contains the pellagra preventive as we have found that it does of the blacktongue preventive. So far as it goes, however, the experience in the human disease is, at least, not inconsistent with that in the experimental disease of the dog.

MILK

The importance of milk as a food and the evidence of its pellagra-preventive value afforded by an epidemiological study of the relation of diet to pellagra incidence (10) and, still more, the direct demonstration by Goldberger and Tanner (11) that milk contains the essential pellagra-preventive factor or factors, led us, very early

in the course of our study, to begin tests of its blacktongue-preventive action. The results of these early tests (which dealt with dried milk, with fresh skim milk, and with a market buttermilk) tended to indicate that milk had but feeble blacktongue-preventive action. For various reasons, which need not be detailed, we did not consider those tests conclusive, and, therefore, have more recently carried out another study of milk (fresh skim milk) the details and results of which we present in the following:

EXPERIMENT 7

This was a test of the blacktongue-preventive action of a fresh skim milk for which we are indebted to Dr. L. A. Rogers, Director of the Research Laboratories of the Bureau of Dairy Industry of the Department of Agriculture. The milk when delivered to us was freshly separated. As a rule, departed from only over the week end or other holiday, this milk in 2-quart glass jars was allowed to stand in an ice box for not more than 24 hours before being used. Then, although already machine separated, as much of the bottom layer as was needed was siphoned off and, after being warmed slightly, offered to the test animals.[1] The milk, unless otherwise specified, was given by drench, an all-metal syringe of convenient capacity being used. The daily dose was at the rate of approximately 30 c. c. per kilogram of normal body weight. It was given as a supplement to basic blacktongue-producing diet No. 123. (Table 1) The test animals were five dogs—numbered 54, 65, 68, 71, and 110. The significant details relating to each of these animals are as follows:

Dog 54.—Bitch. Acquired September 25, 1923. Up to May 26, 1926, served in several experiments and suffered a number of attacks of blacktongue, the occurrence of the latest of which was suggested by an evanescent redness of the mucosa of the floor of the mouth on September 19, 1925. On stock diet for reconditioning from May 26 to August 3, 1926.

August 3, 1926: In good condition; weighs 8.7 kilograms; begins diet No. 123 with a daily supplement of 285 c. c. of skim milk, which this animal laps greedily.

August 4, 1927: Presents to-day, one year since beginning this test, a slight injection of the mucosa of the floor of the mouth.

August 6: The floor of the mouth continues injected. In addition the mucosa of the upper lip presents two reddened patches on each side opposite the canines.

August 7: Lip lesions have about faded out; floor continues somewhat injected.

August 9: Mouth is normal in appearance.

September 7, 1927: In good condition; weighs 8.5 kilograms; has been taking the skim milk, nearly always by lapping, for 13 months. Between August 4 and August 9, 1927, or at the end of one year, presented mild, evanescent signs of blacktongue. Further history not relevant.

Dog 65.—Bitch. Acquired January 28, 1924. Up to May 26, 1925, served in two experiments and suffered two attacks of blacktongue, the second of which

[1] Four samples of this skim milk examined by Assistant Chemist C. G. Remsburg in the Division of Chemistry, Hygienic Laboratory, were found to vary in fat content between 0.05 and 0.40 per cent.

was doubtful and was represented merely by an evanescent reddening of the floor of the mouth and mucosa of cheeks on February 3, 1926. On stock diet for reconditioning from May 26 to August 3, 1926.

August 3, 1926: In good condition; weighs 8.3 kilograms; begins diet No. 123 with a daily supplement of 270 c. c. of skim milk.

September 7, 1927: Has been receiving a daily supplement of 270 c. c. of skim milk by drench since August 3, 1926, or 13 months. Has presented no recognizable evidence of blacktongue during this period. Is in good condition. Weighs 9.3 kilograms. Further history not relevant.

Dog 68.—Bitch. Whelped in the laboratory, November 25, 1923. Up to May 26, 1926, served in two experiments, but did not have blacktongue. On stock diet from May 26 to August 3, 1926.

August 3, 1926: In good condition; weighs 9.3 kilograms; begins diet No. 123 with a daily supplement of 300 c. c. of skim milk by drench.

September 7, 1927: In good condition; weighs 9.8 kilograms. Has been receiving the milk supplement for 13 months. Has presented no recognizable evidence of blacktongue during this period. Further history not relevant.

Dog 71.—Male. Whelped in the laboratory November 25, 1923. Up to May 26, 1926, served in two experiments but had no blacktongue. On stock diet from May 26 to August 3, 1926.

August 3, 1926: In good condition; weighs 10.5 kilograms; begins diet No. 123 with a daily supplement of 330 c. c. of skim milk by drench.

September 9, 1926: Presents to-day, 37 days after beginning the test of skim milk, the first signs of an attack of blacktongue, an injection of the mucosa of the floor of the mouth. Further history not relevant.

Dog 110.—Bitch. Acquired October 29, 1926. Up to December 8, 1926, on stock diet.

December 8, 1926: In good condition; weighs 10.4 kilograms; begins diet No. 123 with a daily supplement of 315 c. c. of skim milk by drench.

September 7, 1927: In good condition; weighs 11.9 kilograms. Has been getting the skim milk daily for 9 months. Has presented no evidence of blacktongue during this period. Experiment is this day discontinued. Further history not relevant.

Results and conclusions.—Of the five test animals, one (dog 71) developed a well marked attack of blacktongue at the end of a period of 37 days; one (dog 54) developed slight transient evidence of an attack at the end of one year; the other three presented no recognizable evidence of blacktongue during the period of observation, which was one year for two and nine months for the third of these animals. Recalling that, in our experience, feeding with basic diet No. 123 has regularly resulted in an attack of blacktongue within a period only exceptionally longer than about two months, it follows that the skim milk supplement exercised a definitely appreciable but not fully complete blacktongue-preventive action. It may be concluded, therefore, that milk contains the blacktongue preventive, but that somewhat more than 30 c. c. daily per kilogram of body weight, at least of skim milk, may be needed to secure complete protection when used to supplement such basic diet as our No. 123.

In this connection it is of interest to recall that, in their study of the pellagra-preventive action of buttermilk, Goldberger and Tanner (11)

found that a supplement of 1,200 c. c. (40 ounces) was adequate for the complete prevention of the disease in their patients and incidentally expressed the opinion that a somewhat smaller quantity might possibly have served equally well. How much smaller was at the time not definitely stated, but we judge, on the basis of general observation and experience with milk, that this could probably have been some 200 or 300 c. c. In other words, it seems to us probable that about 900 or 1,000 c. c. of buttermilk as a supplement to the type of diet received by those patients would have been adequate for pellagra prevention with but little, if any, margin for safety.[1] It thus appears that milk contains the preventive for both blacktongue and pellagra, but, considered in relation to effective quantity, contains it in relatively small amount.

BUTTER

Very early in our study of blacktongue we began an investigation of butter. At the outset this was done in order to determine to what extent, if at all, the action of butter in blacktongue resembled that in pellagra. Working at the Georgia State Sanitarium with butter locally produced, Goldberger and Tanner (11) had found this ineffective in several cases of pellagra in patients weighing 51 to 57.5 kilograms, in spite of a daily consumption that for periods of three to upward of five months had averaged approximately 135 to 145 grams. In order to make the comparison of the effectiveness of butter as rigid as possible, our study in the dog was begun with some of the same butter as that used by Goldberger and Tanner in pellagra. Later, learning that Underhill and Mendel had found butter a potent curative and preventive agent in the Chittenden-Underhill syndrome in the dog (6),[2] a pathological condition which, at that time, it seemed probable might be identical with the experimental disease, blacktongue (12), with which we were working, we extended our study to include a test of butter secured from the same source (a creamery in Vermont) as that of some with which Underhill and Mendel worked. In this connection it may be noted that, since it seemed possible that butter from a northern dairying locality, such as that which formed the source of the butter used by Underhill and Mendel, might be more potent in the factor preventing blacktongue, and thus possibly also pellagra, than butter from the nondairying region in the vicinity of the Georgia State Sanitarium in central Georgia, Goldberger and Wheeler thought it worth while to make some

[1] Since a majority of those patients weighed about 60 kilograms, it would follow that somewhat less than 20 c. c. of buttermilk per kilogram of body weight served in that study as a pellagra preventive. Since, on the other hand, somewhat more than 30 c. c. of skim milk per kilogram of body weight of dog is needed for full prevention of blacktongue, it may be suggested that the dog's requirement for the preventive factor is probably about twice as large as man's per kilogram of body weight

[2] We are under obligation to the courtesy of Professors Underhill and Mendel for advance information of their finding with regard to butter, and for aid in securing for our use a supply of butter from the same source (in Vermont) as that of their own.

pellagra-preventive trials with some of this same northern butter. The results of these trials proved no more favorable, however, than of those previously reported with butter locally produced (1). They concluded, therefore, that while the pellagra preventive may be present in butter, the quantity of butter that must be eaten before its pellagra-preventive action becomes appreciable is so large as to indicate that this preventive, if present in the butter, is present in practically negligible quantity. As will presently be seen, our experience with butter in experimental blacktongue is in harmony with that just cited in pellagra, and thus very different from that reported by Underhill and Mendel (6) (7).

In the study of butter that we wish now to present we have used products from three distinct sources, namely, Milledgeville, Ga.; Beltsville, Md.; New Haven, Conn.

The Milledgeville butter was, as already stated, some of the same butter as that used by Goldberger and Tanner (11) in a study of its pellagra-preventive potency. It was part of the supply of the Georgia State Sanitarium which secured it in batches of a few pounds from farmers of the vicinity. In June, 1923, a considerable quantity of this butter was melted, the fat siphoned into glass jars, and thus sent by express to the Hygienic Laboratory. At the Hygienic Laboratory it was stored in the refrigerator room. This butter—or more precisely, butterfat—will be referred to as our Milledgeville butterfat.

The Beltsville butter was a batch of butter specially prepared for us October 2-3, 1923, from sweet cream of cows, 25 to 50 per cent pasture fed, of the Beltsville farm of the Bureau of Dairy Industry, United States Department of Agriculture, for which we are indebted to Dr. L. A. Rogers, director of its research laboratories. It was kept by us in the laboratory ice box until used.

The butter secured from New Haven was actually from a creamery in Vermont, and, as already explained, was the same as that from which Underhill and Mendel secured their butter. It was laid down early in July, 1924. Some of this butter was used as above stated in a study of pellagra prevention at the Georgia State Sanitarium (1). It was kept in cold storage at New Haven, Conn., until October, when a batch was forwarded to us at the Hygienic Laboratory. At the laboratory it was stored in its original form in wooden tubs or, after conversion into butterfat, in glass jars in the laboratory refrigerator room, from which small batches were, from time to time, withdrawn and kept in an ice box until used. Depending upon whether it was used in its original form or as butterfat, this product will be designated as Vermont butter or Vermont butterfat.

Our study of butter (including butterfat) is detailed in experiments 8-12, which follow:

EXPERIMENT 8

This was, first, a preventive test of Milledgeville butterfat and, second, a therapeutic test of Beltsville butter in immediately succeeding periods in the same animal, dog 47. The significant details are as follows:

Dog 47.—Male. Acquired August 18, 1923. On a stock diet to September 11, 1923.

September 11, 1923: In good condition. Weighs 9.2 kilograms. Begins Milledgeville butterfat diet No. 115, the composition of which is shown in Table 9. It may be remarked that basically and in blacktongue-producing potency this diet is much the same as the diet (No. 34), with which Goldberger and Wheeler (2) first succeeded in inducing blacktongue in the dog.

September 25: Weighs 9.2 kilograms. Daily food consumption during the past two weeks has averaged approximately 970 grams, representing 62 grams of butterfat, or fully 6.5 grams of butterfat per kilogram of body weight.

September 28: There are present this morning, at the end of a period of 17 days of butterfat diet No. 115, the first signs of an attack of blacktongue, an injection of the floor of the mouth, a reddening of the mucosa of the cheeks and of that of the upper lip opposite the canines.

October 4: Given 100 grams of fresh lean beef on September 28, September 29, and on October 2, so as to retard the progress and mitigate the severity of the attack preparatory to treatment with Beltsville butter, which is begun to-day with diet No. 115B, the composition of which is shown in Table 10.

October 16: Weighs 10.6 kilograms. The daily food consumption since the change to Beltsville butter diet No. 115B has averaged approximately 1,080 grams, representing 86 grams of Beltsville butter or fully 8 grams of butter per kilogram of body weight.

October 18: Presents this morning, 14 days since beginning the Beltsville butter diet No. 115B, buccal signs of the beginning of a relapse of the attack of blacktongue, an injection of the floor of the mouth. Further history not relevant.

Result.—The ingestion of the Milledgeville butterfat in a daily quantity that averaged fully 6.5 grams per kilogram of body weight was inadequate to prevent the development of an attack of blacktongue in this animal, nor was the ingestion of the Beltsville butter at a daily rate of fully 8 grams per kilogram of body weight adequate appreciably to effect the further progress or relapse of the attack.

EXPERIMENT 9

This, like the second period of the preceding experiment, was a test of the therapeutic potency of Beltsville butter. It was carried out in two animals, dogs 17 and 29, the significant details and results of which are as follows:

Dog 17.—Bitch. Acquired April 14, 1923. Up to October 16, 1923, served in two experiments and suffered two attacks of blacktongue, the second of which began October 9, 1923.

October 16, 1923: The buccal lesions of blacktongue that made their first appearance a week ago have subsided. Received 100 grams of fresh lean beef, therapeutically, on each of the past three days in order to mitigate the severity and retard the progress of the attack in preparation for the test of butter.

Weighs 10.4 kilograms. Begins Beltsville butter diet No. 115B, the composition of which is shown in Table 10.

October 21: Has been eating well, having regularly consumed all of the daily allowance of 1,000 grams of food, representing 80 grams of Beltsville butter, or fully 7.5 grams of butter per kilogram of body weight. Presents this morning, five days after beginning the butter treatment, faint patches of redness on the mucosa of the upper lip opposite the canine teeth; the mucosa of the floor of the mouth is suggestively injected.

October 22: Mouth appears about normal this morning. Yesterday ate approximately 1,165 grams of food, representing 93 grams of butter.

October 24: Floor of mouth again slightly reddened. Weighs 10.7 kilograms.

October 25: Injection of the floor of the mouth is somewhat more pronounced.

October 27: The buccal lesions of blacktongue have become still more pronounced and more extensive. During the past five days has consumed a daily average of approximately 930 grams of food, representing 75 grams of butter.

October 31: The buccal lesions have faded markedly during the past two or three days. Weighs 11 kilograms. Has consumed during the past four days a daily average of approximately 930 grams of food, representing 75 grams of butter, or fully 6.5 grams of butter per kilogram of body weight.

November 5: The buccal lesions have gradually reappeared during the past four days and are well marked this morning, 21 days after beginning treatment. Weighs 10.8 kilograms. Has consumed during the past five days an average of approximately 920 grams of food, representing 73 grams of butter a day, or fully 6.5 grams of butter per kilogram of body weight. The butter diet, seeming to be ineffective, is discontinued. Further history not relevant.

Dog 29.—Male. Acquired May 9, 1923. Up to October 9, 1923 had experienced two attacks of blacktongue, the second of which began September 30, 1923.

October 9, 1923: The attack of blacktongue that began nine days ago has subsided. Mouth is normal. Received 100 grams of lean fresh beef daily October 3–7 and 50 grams yesterday in order to retard the development and mitigate the severity of the attack in preparation for the test of butter. Weighs 10.4 kilograms. To-day begins Beltsville butter diet No. 115B, the composition of which is shown in Table 10.

October 16: Weighs 11 kilograms. Has eaten daily during the week an average of approximately 950 grams of food, representing 76 grams of Beltsville butter, or fully 6.5 grams of butter per kilogram of body weight.

October 18: Mucosa of the floor of the mouth is slightly reddened.

October 20: Injection of the floor of the mouth is more pronounced this morning.

October 23: Mouth appears about normal this morning. Weighs 11.2 kilograms. Daily food consumption during the past week has averaged 650 grams, representing 52 grams of butter, or fully 4.5 grams of butter per kilogram of body weight.

October 24: Floor of the mouth is again slightly injected.

October 25: Reddening of the mucosa of the floor of the mouth is quite pronounced this morning.

October 27: Reddening of the floor of the mouth persists.

October 30: Mouth is well-nigh normal this morning. Weighs 11.3 kilograms. Daily food consumption during the past week has averaged approximately 680 grams, representing 56 grams of butter or but little short of 5 grams of butter per kilogram of body weight.

November 1: Mouth is again about normal.

November 13: The mucosa of the floor of the mouth has, during the past week, become progressively more intensely reddened. In addition the mucosa of the

upper lip and of the cheeks has also become reddened, so that the animal now (34 days after beginning the Beltsville butter diet) presents well marked buccal lesions of blacktongue. Weighs 11.5 kilograms. The average daily food consumption during the past two weeks fell to 600 grams, representing 48 grams of butter or fully 4 grams per kilogram of body weight. Further history not relevant.

Result.—Thus, as in experiment 8, notwithstanding that the treatment with Beltsville butter was begun in both animals under favorable conditions, and that both ingested the butter at what would seem to be a liberal rate (which at the outset was fully 7.5 and 6.5 grams per kilogram of body weight, respectively), in neither animal was the progress of the attack appreciably affected.

EXPERIMENT 10

This was a further test of the blacktongue-preventive potency of Milledgeville butterfat which was now, it may be noted, 15 months old. The test animals were three dogs, numbered 5, 13, and 48. Each of the dogs was daily offered a liberal allowance of diet No. 180A containing the butterfat. The composition of this diet is shown in Table 11. The significant details relating to each animal are as follows:

Dog 5.—Bitch. Acquired November 8, 1921. Up to August 19, 1924, served in a number of experiments and suffered three attacks of blacktongue, the latest of which began August 2, 1924. On stock diet for reconditioning from August 19 to September 23, 1924.

September 23, 1924: In good condition. Weighs 7.7 kilograms. Begins Milledgeville butterfat diet No. 180A. (Table 11.)

October 1: Has been eating well. Weighs 7.8 kilograms. Has consumed during the past eight days a daily average of approximately 820 grams of food, representing 40 grams of butterfat, or 5 grams of butterfat per kilogram of body weight.

November 1: Has continued to eat well during the past month. Weighs 8.2 kilograms. Has regularly consumed the daily allowance of 800 grams of food, representing 38 grams of butterfat or fully 4.5 grams of butterfat per kilogram of body weight.

December 1: Food consumption has held up well. Weighs 8 8 kilograms. Has taken daily during the past month an average of approximately 770 grams of food, representing 37 grams of butterfat or fully 4 grams of butterfat per kilogram of body weight.

December 23: This morning, at the end of a period of 91 days, presents the first signs of an attack of blacktongue, a reddening of the mucosa of the floor of the mouth. Weighs 8.4 kilograms. Food consumption fell off markedly after the first of the present month, the daily average for the past 22 days being but 560 grams, which represents approximately 27 grams of butterfat or fully 3 grams of butterfat per kilogram of body weight. Further history not relevant.

Dog 13.—Male. Acquired April 7, 1923. Up to August 19, 1924, served in several experiments and suffered five attacks of blacktongue, of which the latest began July 11, 1924. On reconditioning diet from August 19 to September 23, 1924.

September 23, 1924: In good condition, weighs 9 kilograms, begins Milledgeville butterfat diet No. 180A.

October 1: Has been eating well. During the past eight days has consumed an average of approximately 935 grams of food, representing 45 grams of Milledgeville butterfat, or approximately 5 grams per kilogram of body weight.

November 1: Weighs 9.8 kilograms, has continued to eat well having regularly consumed during October the daily allowance of 1,000 grams of food, representing approximately 48 grams of butterfat, or fully 4.5 grams of butterfat per kilogram of body weight.

November 11: Weighs 10 kilograms. During the past 10 days has regularly consumed all of the daily allowance of 1,000 grams of food, representing 48 grams of butterfat.

December 1: Weighs 10 kilograms. During the past 20 days appetite was somewhat diminished. The daily food consumption for this period averages approximately 845 grams, representing 40 grams of butterfat, or approximately 4 grams of butterfat per kilogram of body weight.

January 1, 1925: Weight was 9.9 kilograms day before yesterday. Food consumption was further reduced during the past month; the daily intake has averaged but 715 grams, representing approximately 34 grams of butterfat, or a little short of 3.5 grams of butterfat per kilogram of body weight.

January 6: This morning, at the end of a period of 105 days, presents the first signs of an attack of blacktongue, a reddening of the mucosa of the floor of the mouth and of that of the cheeks. During the past five days the daily food consumption has averaged approximately 655 grams, representing 31 grams of butterfat. Weighs 9.8 kilograms. Further history not relevant.

Dog 48.—Bitch. Acquired August 20, 1923. Up to August 5, 1924, served in several experiments and suffered two attacks of blacktongue, of which the second began May 20, 1924. From August 5 to September 23, 1924, was on a reconditioning diet.

September 23, 1924: In good condition. Weighs 6.2 kilograms. Begins Milledgeville butterfat diet No. 180A.

October 1: Weighs 6.6 kilograms. Has been eating well. Has regularly consumed all of the daily allowance of 800 grams of food, representing 38 grams of Milledgeville butterfat or fully 5.5 grams of butterfat per kilogram of body weight.

October 28: Weighs 7 kilograms. Has continued to eat well, regularly consuming all of the daily allowance of 800 grams of food, representing 38 grams of butterfat, or slightly short of 5.5 grams of butterfat per kilogram of body weight.

November 4: Weighs 6.8 kilograms. Has been leaving some of the food nearly every day during the past seven days. The daily consumption has averaged approximately 580 grams, representing about 28 grams of butterfat, or approximately 4 grams of butterfat per kilogram of body weight.

December 2: Weighs 6.8 kilograms. During the past four weeks the daily food consumption has averaged approximately 565 grams, representing about 27 grams of butterfat, or slightly short of 4 grams of butterfat per kilogram of body weight.

December 30: Weighs 6.8 kilograms. The daily food consumption during the past four weeks has averaged approximately 540 grams, representing 26 grams of butterfat, or fully 3.5 grams of butterfat per kilogram of body weight.

January 27, 1925: Weighs 6.9 kilograms. During the past four weeks the daily food consumption has averaged approximately 540 grams, representing about 26 grams of butterfat, or slightly over 3.5 grams of butterfat per kilogram of body weight.

February 24: Weighs 6.7 kilograms. During the past four weeks the daily food consumption has averaged approximately 440 grams, representing about 21 grams of butterfat, or at a rate of approximately 3 grams of butterfat per kilogram of body weight.

March 10: During the past two weeks food consumption declined to a daily average of approximately 320 grams, representing 15 grams of butterfat. Weight has declined to 6.2 kilograms. Presents this morning, 168 days since beginning the Milledgeville butterfat diet, the first signs of an attack of blacktongue, a reddening of the mucosa of the floor of the mouth and slightly reddened patches on the mucosa of the upper lip opposite the canines. Further history not relevant.

Result.—It appears from the foregoing that all three test animals developed blacktongue, notwithstanding a liberal daily ingestion of the butterfat. The first significant buccal signs of the disease made their appearance in these animals at the end of 91, 105, and 168 days, respectively. This result, it may be noted, is in harmony with the result of the test of the same butterfat in Experiment 8 when it was but 3 months old.

EXPERIMENT 11

This was a study of Milledgeville butterfat (diet No. 180A) and of Vermont butterfat (diets No. 180B and No. 180C) in separate but immediately succeeding periods in each of four test animals, namely, dogs 9, 44, 66, and 73. When its use was begun, the Milledgeville butterfat was 15 to 16 months old, while the Vermont product, when it came into use, was about 6 months old in one case (dog 9) and about 11 months old in each of the other three cases. The significant details relating to each of the animals are briefly as follows:

Dog 9.—Male. Acquired April 1, 1923. Has served in several experiments and has suffered five attacks of blacktongue, of which the latest began July 31, 1924. On reconditioning stock diets from August 19 to October 1, 1924.

October 1, 1924: In good condition. Weighs 10.5 kilograms. Begins Milledgeville butterfat diet No. 180A, the composition of which is shown in Table 11.

November 11: Weighs 11.6 kilograms. Has been eating well, regularly consuming the daily allowance of 1,100 grams of food, representing approximately 53 grams of Milledgeville butterfat, or fully 4.5 grams of butterfat per kilogram of body weight.

November 25: Weighs 12 kilograms. Appetite has been less consistently good during the past two weeks. The daily food consumption has averaged approximately 1,030 grams, representing 49 grams of butterfat, or 4 grams per kilogram of body weight.

December 9: Weighs 11.7 kilograms. Appetite still further dulled. Daily food consumption during the past two weeks averages approximately 800 grams, representing 38 grams of butterfat, or upward of 3 grams per kilogram of body weight.

December 11: Presents this morning a slight, somewhat suggestive, streaky injection of the floor of the mouth.

December 18: The streaky redness of the floor persisted a few days, then faded. Mouth is about normal.

December 23: Weighs 11.7 kilograms. Food consumption during the past two weeks has averaged approximately 880 grams per day, representing 42 grams of butterfat, or fully 3.5 grams per kilogram of body weight.

December 25: This morning, at the end of a period of 85 days, presents the first definite signs of an attack of blacktongue, an injection of the mucosa of the floor of the mouth.

January 3, 1928: During the past 11 days food consumption has been considerably reduced, the daily average for this period being approximately 550 grams, representing 26 grams of butterfat. The buccal lesions (erythematous bands on the mucosa of the upper lip, reddened mucosa of the cheeks and of the floor of the mouth) now being well marked and the appetite having become reduced, it is deemed desirable to try to retard or arrest the progress of the attack preparatory to a change in the butter of the diet. Accordingly, 22 grams of dried brewery yeast is administered to-day.

January 4: Another dose of 22 grams of dried brewery yeast is administered and the diet is changed to Vermont butterfat diet No. 180B, the composition of which (shown in Table 11) is identical, except as to the butterfat, with that of Milledgeville butterfat diet No. 180A.

January 6: A third dose of 22 grams of yeast was administered yesterday. Yeast treatment is discontinued effective to-day. All buccal lesions have faded, and the appetite seems to be restored. Ate all food offered yesterday and the day before. Weighs 11.7 kilograms.

January 13: Weighs 11.8 kilograms. Has been eating well during the past week, regularly consuming the daily allowance of 1,100 grams of food, representing approximately 53 grams of Vermont butterfat, or fully 4 grams per kilogram of body weight.

February 3: Weighs 11.5 kilograms. Appetite has become dulled during the past week. The daily food consumption during this period has averaged approximately 730 grams, representing 35 grams of butterfat, or approximately 3 grams per kilogram of body weight.

February 24: Weighs 10.9 kilograms. Appetite has become further reduced during the past three weeks. The daily food consumption has averaged but 470 grams, representing approximately 23 grams of butterfat, or fully 2 grams per kilogram of body weight. Presents to-day, 51 days after the change from the Milledgeville to the Vermont butterfat diet, the first buccal signs of an attack, or perhaps of a relapse, of blacktongue. Further history not relevant.

Dog 44.—Male. Whelped in the laboratory June 26, 1923. Up to August 19, 1924, served in two experiments and suffered two attacks of blacktongue, the latest of which began August 13, 1924. On a reconditioning diet from August 19 to September 23, 1924.

September 23, 1924: In good condition. Weighs 11.8 kilograms. Begins Milledgeville butterfat diet No 180A. (Table 11.)

October 1: Weighs 11.6 kilograms. Has been eating well. Food consumption has averaged approximately 1,175 grams per day, representing about 59 grams of butterfat, or approximately 5 grams per kilogram of body weight.

November 1: Weighs 11.8 kilograms. Daily food consumption during the past month has averaged approximately 1,380 grams, representing 66 grams of butterfat, or approximately 5.5 grams per kilogram of body weight.

December 1: Weighs 11.5 kilograms. Daily food consumption for November has averaged approximately 1,370 grams, representing about 65 grams of butterfat or approximately 5.5 grams per kilogram of body weight.

December 28: Weighs 10.6 kilograms. Food consumption has gradually diminished. During the past 22 days it has averaged approximately 990 grams,

representing 47 grams of butterfat per day, or slightly over 4 grams per kilogram of body weight.

December 27: This morning, 95 days since the butterfat diet was begun, the mucosa of the floor of the mouth is found very suggestively reddened.

December 28: Mouth appears normal.

January 1, 1925: Food consumption during the past nine days has been much better than during the earlier part of December, averaging approximately 1,380 grams of food, representing 66 grams of butterfat daily.

February 1: Weighs 10.9 kilograms. The daily food consumption during January has averaged approximately 1,430 grams, representing about 68 grams of butterfat, or fully 6 grams per kilogram of body weight

March 1: Weighs 10.9 kilograms. During the past month the daily food consumption has averaged approximately 1,300 grams, representing about 62 grams of butterfat.

April 1: Weighs 10.7 kilograms. During March the daily food consumption has averaged approximately 1,380 grams, representing 66 grams of butterfat, or approximately 6 grams per kilogram of body weight.

May 1: During April the daily food consumption averaged approximately 1,500 grams, representing 72 grams of butterfat.

May 26: Weighs 12.2 kilograms. Since the beginning of this month the daily food consumption has averaged approximately 1,470 grams, representing about 71 grams of butterfat, or fully 5.5 grams per kilogram of body weight. There has been no evidence suggesting blacktongue since the evanescent reddening of the mucosa of the floor of the mouth noted December 27, 1924, five months ago. Begins this day Vermont butterfat diet No. 180C, the composition of which is shown in Table 11.

June 1: The daily food consumption since the change in diet has averaged approximately 1,200 grams, representing about 57 grams of Vermont butterfat.

July 1: Weighs 12 kilograms. Food consumption during June has averaged approximately 1,170 grams, representing about 56 grams of butterfat per day, or fully 4.5 grams per kilogram of body weight.

July 17: Three days ago weighed 12 kilograms. Daily food consumption since the beginning of this month has averaged approximately 1,050 grams, representing 50 grams of butterfat, or approximately 4 grams of butterfat per kilogram of body weight.

Presents this day—52 days since beginning the Vermont butterfat diet—a suggestive reddening of the floor of the mouth. A reconditioning diet is begun this day.

July 18: The injection of the floor of the mouth has faded. Further history not relevant.

Dog 66.—Male. Whelped in the laboratory November 25, 1923. Reared on stock diets. Between April 22 and June 9, 1924, served in one experiment without any manifestations of blacktongue. On stock diet between June 9, 1924, and September 23, 1924.

September 23, 1924: In good condition. Weighs 10.4 kilograms. Begins Milledgeville butterfat diet No. 180A. (Table 11.)

October 1: Weighs 10.2 kilograms. Since beginning this test has regularly eaten all of the daily allowance of 1,100 grams of food, representing about 53 grams of Milledgeville butterfat, or approximately 5 grams per kilogram of body weight.

October 8: Weighs 10.1 kilograms. Has regularly been eating all of the daily allowance of 1,200 grams of food during the past week.

October 22: Weighs 10.4 kilograms. During the past two weeks the daily food consumption has averaged approximately 1,420 grams, representing 68 grams of butterfat, or fully 6 grams per kilogram of body weight.

November 4: Weighs 11 kilograms. During the past two weeks has been regularly consuming all of the daily allowance of 1,700 grams of food, representing about 82 grams of butterfat, or almost 7.5 grams per kilogram of body weight.

November 11: Weighs 11 kilograms. During the past week the food consumption has averaged approximately 1,680 grams a day, representing 81 grams of butterfat, or fully 7 grams per kilogram of body weight. The mucosa of the floor of the mouth is this morning, 49 days since beginning the Milledgeville butterfat diet, suggestively reddened.

November 12: Injection of the floor of the mouth about as yesterday.

November 14: Injection of the floor of the mouth has become much reduced.

November 16: The mucosa of the floor of the mouth is normal in appearance this morning. During the past five days the appetite appears to have been slightly dulled, the daily food consumption averaging approximately 1,340 grams, representing 64 grams of butterfat.

December 2: Weighs 11 kilograms. During the past 16 days the food consumption has averaged approximately 1,570 grams, representing 75 grams of butterfat, or slightly short of 7 grams per kilogram of body weight.

January 6, 1925: Weighs 11.4 kilograms. During the past five weeks the daily food consumption has averaged approximately 1,510 grams, representing 72 grams of butterfat, or fully 6 grams per kilogram of body weight.

February 3: Weighs 10.7 kilograms. During the past four weeks the daily food consumption has been somewhat diminished, averaging approximately 1,450 grams per day.

March 3: Weighs 10.5 kilograms. During the past four weeks the daily food consumption has averaged approximately 1,440 grams, representing 69 grams of butterfat, or nearly 6.5 grams per kilogram of body weight.

March 5: Since the subsidence of the suggestive reddening of the mucosa of the floor of the mouth—first noted on November 11, 1924, four months ago—this animal has presented no buccal lesions suggestive of blacktongue until this morning. This morning, 163 days since beginning the test, there is again present a suggestive injection of the mucosa of the floor of the mouth.

March 7: Floor of mouth continues suggestively reddened.

March 8: Mouth again appears normal.

March 10: Weighs 10.9 kilograms. During the past week has regularly eaten the daily allowance of 1,700 grams of food, representing approximately 82 grams of butterfat, or fully 7 grams per kilogram of body weight.

March 26: Mucosa of floor of mouth again slightly but suggestively reddened.

March 27: Mouth again normal.

April 7: Weighs 10.5 kilograms. During the past four weeks the daily food consumption has averaged approximately 1,310 grams, representing 63 grams of butterfat, or approximately 6 grams per kilogram of body weight.

May 26: Weighs 11 kilograms. During the past seven weeks the daily food consumption has averaged approximately 1,475 grams, representing 71 grams of butterfat. Has presented nothing suggesting blacktongue since the evanescent injection of the floor of the mouth noted March 26. Begins this day Vermont butterfat diet No. 180C. (Table 11.)

June 11: Two days ago weighed 10.8 kilograms. Food consumption during the past 16 days has been somewhat diminished, averaging approximately 1,190 grams a day, which represents 57 grams of Vermont butterfat, or fully 5 grams of butterfat per kilogram of body weight.

Presents this morning, 16 days after beginning the Vermont butterfat diet and 261 days since beginning the test, definite buccal signs of an attack of blacktongue, a well-marked reddened patch on the mucosa of the upper lip opposite the canines on both sides, slight reddening of the mucosa of the cheeks and marked reddening of the floor of the mouth. Further history not relevant.

Dog 78.—Bitch. Acquired March 19, 1924. Up to August 18, 1924, served in one experiment. Presented evanescent signs suggesting blacktongue on July 12, 1924. From August 19 to September 23, 1924, on reconditioning diets.

September 23, 1924: In good condition. Weighs 10.4 kilograms. Begins Milledgeville butterfat diet No. 180A. (Table 11.)

October 21: Weighs 9.7 kilograms. Daily food consumption during the past four weeks has averaged approximately 660 grams, representing 32 grams of Milledgeville butterfat, or fully 3 grams per kilogram of body weight.

November 18: Weighs 9.6 kilograms. During the past four weeks the daily food consumption has averaged 610 grams, representing 29 grams of butterfat, or approximately 3 grams per kilogram of body weight.

December 16: Weighs 9.4 kilograms. During the past four weeks the daily food consumption has averaged approximately 750 grams, representing 36 grams of butterfat, or fully 3.5 grams per kilogram of body weight.

January 13, 1925: Weighs 9.6 kilograms. During the past four weeks the daily food consumption has averaged approximately 730 grams, representing 35 grams of butterfat, or fully 3.5 grams per kilogram of body weight.

March 10: Weighs 10.7 kilograms. During the past eight weeks the daily food consumption has averaged approximately 680 grams, representing 33 grams of butterfat, or approximately 3 grams per kilogram of body weight.

April 7: Weighs 9.4 kilograms. Appetite has for some time been increasingly variable and, in general, considerably diminished. During the past four weeks the daily food consumption has averaged approximately 460 grams, representing 22 grams of butterfat, or fully 2 grams per kilogram of body weight.

May 26: Weighs 9.8 kilograms. During the past seven weeks appetite has in general been better. The daily food consumption for this period has averaged approximately 720 grams, representing 35 grams of Milledgeville butterfat, or approximately 3.5 grams per kilogram of body weight. Begins Vermont butterfat diet No. 180C. (Table 11.)

June 23: Weighs 10 kilograms. During the past four weeks the daily food consumption has averaged approximately 690 grams, representing 33 grams of Vermont butterfat or fully 3 grams per kilogram of body weight.

July 7: Weighs 9.7 kilograms. During the past two weeks the daily food consumption has averaged approximately 600 grams, representing 29 grams of butterfat, or approximately 3 grams per kilogram of body weight.

July 11: The mucosa of the floor of the mouth presents a very suggestively reddened area at about its center this morning—46 days after beginning the Vermont butterfat diet, and 291 days after beginning the Milledgeville butterfat diet.

July 13: The injection noted day before yesterday has faded. Weighs 9.8 kilograms.

July 17: Food consumption during the past 10 days has averaged approximately 640 grams, representing 31 grams of butterfat, or fully 3 grams per kilogram of body weight. The feeding with the butterfat diet is this day discontinued. During the period of 297 days of the butterfat feeding this animal presented the suggestive but very evanescent indications of blacktongue noted July 11, 1925.

Result.—We find, then, that each of the four test animals developed some evidence of blacktongue which was definitely marked in two, dogs 9 and 66, but was not more than strongly suggestive in each of the other two. The amount of butterfat ingested daily varied with each animal and in the same animal at different times in accordance with variations in appetite during the progress of the feeding. The daily rate at its highest varied among the dogs between 3.5 and 7 grams per kilogram of body weight for the Milledgeville butterfat and between 3 and 5 grams for the Vermont product. It is notable that the highest rate of consumption was in one of the dogs (dog 66) that developed a definitely recognizable attack of blacktongue.

EXPERIMENT 12

This was a preventive test of the Vermont butterfat and was carried out in four animals, dogs 52, 60, 63, and 64. The butter was about 3 months old when the feeding of the first three of these animals began and about 7 months old when the feeding of the fourth began. The butterfat was incorporated in two diets—No. 180B (Table 11) and No. 180C (Table 11), respectively. These diets were offered separately in immediately succeeding periods to each of three of the test dogs (dogs 52, 60, and 64). In the fourth animal (dog 63) the feeding comprised but a single period and was with diet No. 180B. These diets differed in but one respect, namely, that No. 180C contained no tomato juice. The elimination of tomato juice from the diet was decided upon when certain other of our studies indicated what had not been suspected theretofore—that tomato juice might itself possess preventive action and thus by its inclusion, even in small amounts, tend to affect the result of the feeding. The significant details relating to each of the test dogs are briefly presented in the following:

Dog 52.—Bitch. Acquired September 25, 1923. Has served in several experiments and has suffered three attacks of blacktongue, the latest of which began July 31, 1924. On reconditioning diets from August 19 to October 15, 1924.

October 15, 1924: In good condition. Weighs 9.8 kilograms. Begins Vermont butterfat diet No. 180B. (Table 11.)

October 28: Weighs 9.8 kilograms. Has regularly consumed the daily offering of 1,000 grams of food, representing 48 grams of Vermont butterfat, or slightly less than 5 grams per kilogram of body weight.

November 25: Weighs 10.4 kilograms. Appetite continues excellent. Only once during the past four weeks was any (about 50 grams) of the daily allowance of 1,000 grams left uneaten.

February 10, 1925: Appetite continued excellent throughout the past 11 weeks. Only twice during this period was any (490 grams and 150 grams, respectively) of the daily allowance of 1,000 grams left uneaten. Weight has gradually risen and is 11.5 kilograms to-day.

February 24: Weighs 11.4 kilograms. During the past two weeks appetite has been variable and the food consumption was diminished, averaging approximately 700 grams, representing 34 grams of butterfat, daily.

March 24: Appetite has continued variable and became further dulled during the past four weeks, the daily food consumption averaging approximately 540 grams, representing 26 grams of butterfat. Weighs 9.9 kilograms.

Presents this morning, 157 days since beginning the Vermont butterfat diet, the first signs of blacktongue, a streaky reddening of the mucosa of the floor of the mouth.

March 25: The reddening of the mucosa of the floor of the mouth is more extensive and more vivid.

March 26: The reddening of the floor of the mouth persists.

March 27: The mouth lesion has completely faded.

March 31: Weighs 10.3 kilograms. During the past four days the appetite has been excellent, the animal regularly eating all of the daily allowance of 1,000 grams of food, representing 48 grams of butterfat, or approximately 4.5 grams of butterfat per kilogram of body weight.

April 14: During the past two weeks has regularly eaten all of the daily allowance of 1,000 grams of food. Weighs 10.6 kilograms.

April 28: Left some of the daily allowance of food four times during the past two weeks so that the daily food consumption has averaged 860 grams, representing 41 grams of butterfat. Weighs 10.5 kilograms.

May 12: During the past two weeks food consumption again was excellent, the daily allowance of 1,000 grams of food, representing 48 grams of butterfat, being regularly consumed. Weighs 10.6 kilograms.

May 26: Appetite variable during past two weeks. Daily food consumption has averaged approximately 830 grams, representing 40 grams of butterfat. Weighs 10.3 kilograms. Begins to-day Vermont butterfat diet 180C, thus excluding tomato juice from the ration.

June 23: Weighs 10.2 kilograms. During the past four weeks the daily food consumption has averaged approximately 930 grams, representing 45 grams of butterfat, or approximately 4.5 grams of butterfat per kilogram of body weight.

July 7: Daily food consumption during the past two weeks has averaged approximately 780 grams, representing 37 grams of butterfat. Weighs 10.3 kilograms.

July 17: During the past 10 days the daily food consumption has averaged approximately 900 grams, representing 43 grams of butterfat. Three days ago weighed 10.2 kilograms. Is in good condition. The butterfat feeding is discontinued this day, 275 days after it began. During this period transient buccal signs of blacktongue were in evidence between March 24 and March 27.

Dog 60.—Male. Whelped in the laboratory November 4, 1923. Reared and maintained on stock diets up to October 15, 1924.

October 15, 1924: In good condition. Weighs 6.5 kilograms. Begins Vermont butterfat diet No. 180B.

December 16: Weighs 7.7 kilograms. Appetite has been excellent. Has regularly consumed all of the daily allowance of 1,100 grams of food, representing approximately 53 grams of butterfat, or fully 6.5 grams per kilogram of body weight.

December 30: During the past two weeks has twice left a little (220 grams and 140 grams, respectively) of the daily allowance of 1,100 grams of food. Weighs 7.8 kilograms.

January 13, 1925: Appetite has been quite variable and food consumption somewhat reduced during the past two weeks. The daily food consumption has

averaged approximately 820 grams. representing 39 grams of butterfat. Weighs 7.3 kilograms.

January 17: Presents a desquamative lesion of the skin of the scrotum; it was first observed about two weeks ago.

February 10: During the past four weeks the daily food consumption has averaged approximately 1,020 grams, representing 50 grams of butterfat. Weighs 7.4 kilograms.

February 28: Scrotal lesion persists and has become somewhat more extensive.

March 10: During the past four weeks the daily food consumption has averaged approximately 970 grams, representing 47 grams of butterfat. Weighs 7.5 kilograms.

March 24. Desquamation of skin of scrotum persists.

April 7: During the past four weeks the appetite has continued to be variable. The daily food consumption has averaged approximately 830 grams, representing 40 grams of butterfat. Weighs 7.1 kilograms.

May 26: During the past seven weeks the appetite continued variable. The daily food consumption has averaged approximately 880 grams, representing 42 grams of butterfat. Weighs 7 kilograms. Begins this day Vermont butterfat diet No. 180C.

June 23: Appetite has diminished further during the past four weeks, the daily food consumption averaging approximately 730 grams, representing 35 grams of butterfat. Weighs 6.8 kilograms.

July 14: During the past three weeks the daily food consumption became further reduced, averaging but 510 grams, which represent 24 grams of butterfat. Weighs 6.4 kilograms. Presents this morning, 49 days since the modification in diet eliminating tomato juice, and 272 days since the beginning of the butterfat diet, the first buccal signs of an attack of blacktongue, erythematous bandlike lesions on the mucosa of the upper lip. The scrotum shows some ragged tabs of epidermal flakes marking the periphery of the lesion that has persisted in variable degree for about six months. Further history not relevant.

Dog 63.—Male. Whelped in the laboratory November 4, 1923. Has served in one experiment and suffered an attack of blacktongue, which began June 2, 1924. On reconditioning diets from June 3 to October 15, 1924.

October 15, 1924: In good condition. Weighs 7 kilograms. Begins Vermont butterfat diet No. 180B.

December 30: Weighs 8 kilograms. Appetite has been uniformly excellent. Has regularly consumed the daily allowance of 1,200 grams of food, representing approximately 58 grams of the Vermont butterfat, or fully 7 grams per kilogram of body weight.

February 24, 1925: During the past two months the appetite has been variable and the food consumption has been somewhat diminished, averaging approximately 1,040 grams a day which represents approximately 50 grams of butterfat. Weighs 7.4 kilograms.

February 28: Has for some time presented an ill-defined, mealy sort of desquamation of the skin of the scrotum. It is now more marked and involves nearly all of the ventral aspect of the scrotum, which is also reddened.

March 5: The scrotal lesion has persisted. In addition there are present this morning, 141 days since beginning the butterfat diet, the first buccal signs of an attack of blacktongue, a slight reddening of the mucosa of the floor of the mouth. Appetite during the past nine days has been fairly good. The daily food consumption has averaged 1,110 grams, representing 53 grams of butterfat. Further history not relevant.

Dog 64.—Bitch. Whelped in the laboratory November 4, 1923. On stock diets to February 28, 1925.

February 28, 1925: In good condition. Weighs 6.8 kilograms. Begins Vermont butterfat diet No. 180B.

March 17: Weighs 6.8 kilograms. Appetite has been excellent. Has regularly consumed all of the daily allowance of 1,000 grams of food, representing approximately 48 grams of the Vermont butterfat, or at a rate of approximately 7 grams of butterfat per kilogram of body weight.

March 31: During the past two weeks the daily food consumption was slightly reduced, averaging approximately 870 grams representing 42 grams of butterfat. Weighs 6.7 kilograms.

May 26: During the past eight weeks the appetite has been variable; the daily food consumption has averaged approximately 860 grams, which represents 41 grams of butterfat. Weighs 6.8 kilograms.

Begins to-day Vermont butterfat diet No. 180C, thus excluding tomato juice from the ration.

June 23: During the past four weeks the appetite has become increasingly capricious. The daily food consumption has averaged approximately 710 grams, representing 34 grams of butterfat.

June 27: Presents this morning, 32 days since beginning the butterfat diet without tomato juice, and 114 days since beginning the test of Vermont butterfat, a suggestive injection of the mucosa of the floor of the mouth.

June 28: The reddening of the floor of the mouth has faded out.

July 14: During the past three weeks the appetite continued capricious. The daily food consumption has averaged 770 grams, representing 37 grams of butterfat. Weighs 6.9 kilograms.

July 17: Animal is in good condition. Has presented no further evidence suggestive of blacktongue since the evanescent injection of the floor of the mouth noted three weeks ago. Experiment is discontinued at the end of an observation period of 139 days for this animal.

Results and conclusions.—Thus it appears that all four test dogs developed some evidence of blacktongue. This was of such a character in three of the animals as to permit of a definite diagnosis in them, but was too slight in the fourth (dog 64) to be more than suggestive. It should, perhaps, be noted that in the latter animal the experimental period was relatively short—139 days—so that the possibility is not excluded that more definite evidence would have appeared if that period had been longer. In the three animals with definitely recognizable attacks, these attacks began at the end of 157, 272, and 141 days, respectively. It is pertinent to note that the consumption of the experimental diets was such as to represent during certain high periods an ingestion of butterfat that varied among the dogs between 5 and 7 grams per kilogram of body weight.

Turning now to a consideration of the results of the experiment with butter (including butterfat) as a whole, we find that in the three animals (dogs 47, 17, and 29) in which it was tested by the curative procedure, no beneficial effect was recognized, although in each instance treatment was begun under very favorable conditions and with, in effect, very large doses of a then recently prepared (Beltsville) butter. In the preventive tests 12 dogs were used; all developed some evidence of blacktongue, but this was slight, at most only sugges-

tive, in three, or 25 per cent of them. In those in which a definite attack was recognizable, this began in all but one (dog 47) at the end of unusually long periods. This delay in the onset, coupled with the large proportion of animals presenting but slight and uncertain evidence of an attack, suggests that the butter (including the butterfat) had an appreciable preventive action. Considered in relation to dosage, that is, in relation to the quantities of butter ingested per kilogram of body weight of dog, the preventive potency of the butter would seem to have been of a rather feeble order. This appears, perhaps, more clearly if one considers that the average human adult male would have to ingest upward of 350 grams of butterfat a day to equal relatively the average amount ingested by some of the dogs. Even allowing for the relatively smaller requirement by the human, which, as suggested by our experience with milk (see preceding section), would appear to be about one-half that of the dog when related to body weight, the amount of butterfat that would have to be ingested by the average human adult male for complete protection would have to exceed 175 grams per day. It would seem permissible to conclude, therefore, that, while not devoid of it, butter is a relatively very poor source of the blacktongue preventive, a conclusion that, as above already remarked, is in harmony with the experience with butter in human pellagra.

COD-LIVER OIL

The well-known richness of cod-liver oil in certain vitamins very early suggested the desirability of investigating it as a possible source of the blacktongue preventive. Tests of the curative and preventive action of cod-liver oil were therefore undertaken concurrently with some of our earlier tests of butter.

The cod-liver oil used in this study was some of the same supply as that tested in pellagra prevention by Goldberger and Tanner (11) at the Georgia State Sanitarium, and by them found ineffective when ingested by their patients at a daily rate of 2 grams per kilogram of body weight. It may be noted that when tested in rats this cod-liver oil was found to be rich in vitamin A (unpublished data).

Curative tests with this oil in four dogs with blacktongue with a daily dosage of 2 grams per kilogram of body weight failed in every instance to effect any appreciable beneficial result. Since interpretation of the preventive test is beset with fewer difficulties than the curative, and can therefore be made with greater confidence of its soundness, we carried out the following experiment:

EXPERIMENT 13

This was a test of the blacktongue preventive action of the beforementioned cod-liver oil. The oil was incorporated in a diet, No. 114, the composition of which is shown in Table 9, and suitable calorie

portions were offered daily to each of three test animals—dogs 17, 29, and 48. The significant details relating to each of these dogs are as follows:

Dog 17.—Bitch. Acquired April 14, 1923. Up to August 10, 1923, served in one experiment and suffered an attack of blacktongue, which began July 3, 1923. On a stock diet from August 10 to September 11, 1923.

September 11, 1923: In good condition. Weighs 11.1 kilograms; begins test diet No. 114. (Table 9.)

September 18: Weighs 11 kilograms. Daily food consumption during the week since beginning the test has averaged approximately 875 grams, representing 56 grams of cod-liver oil, or approximately 5 grams of the oil per kilogram of body weight.

September 25: Weighs 10.7 kilograms. Daily food consumption during the past week has averaged approximately 895 grams, representing 57 grams of cod-liver oil, or fully 5 grams of the oil per kilogram of body weight.

October 2: Weighs 10.3 kilograms. Appetite has fallen off. The daily food consumption during the past week has averaged approximately 700 grams, representing 45 grams of cod-liver oil, or fully 4 grams per kilogram of body weight.

October 9: Weighs 10.2 kilograms. The daily food consumption during the past week has averaged approximately 655 grams, representing 42 grams of cod-liver oil, or 4 grams of oil per kilogram of body weight.

Presents this morning, at the end of a period of 21 days, the first signs of an attack of blacktongue, an injection of the floor of the mouth and reddening of the anterior faucial pillars. Further history not relevant.

Dog 29.—Male Acquired May 9, 1923. Up to July 27, 1923, served in one experiment and suffered an attack of blacktongue, which began July 23, 1923. On a stock diet from July 27 to September 11, 1923.

September 11, 1923: In good condition; weighs 11 kilograms; begins diet No. 114.

September 18: Weighs 10.5 kilograms. Daily food consumption during the week since beginning the cod-liver diet has averaged approximately 650 grams, representing 42 grams of cod-liver oil, or approximately 4 grams of oil per kilogram of body weight.

September 25: Weighs 10.4 kilograms. Daily food consumption during the past week has averaged approximately 605 grams, representing 38 grams of cod-liver oil, or fully 3.5 grams per kilogram of body weight.

September 30: Presents this morning, at the end of a period of 19 days, the first evidence of an attack of blacktongue, an injection of the floor of the mouth. Further history not relevant.

Dog 48.—Bitch. Acquired August 20, 1923. On stock diet to September 11, 1923.

September 11, 1923: In good condition. Weighs 5.9 kilograms. Begins test diet No. 114.

October 2: Weighs 5.5 kilograms. The daily food consumption during the three weeks since beginning this test has averaged approximately 565 grams, representing 36 grams of cod-liver oil, or fully 6 grams of the oil per kilogram of body weight.

October 30: Weighs 5.7 kilograms. Daily average food consumption during the past four weeks has been approximately 625 grams, representing 40 grams of cod-liver oil, or approximately 7 grams of the oil per kilogram of body weight.

November 6: Weighs 5.4 kilograms. Presents this morning, 56 days after beginning the test diet, the first evidence of an attack of blacktongue, an injection of the floor of the mouth.

Result and conclusion.—All three test animals developed blacktongue, the first signs of which appeared at the end of 21, 19, and 56 days, respectively, notwithstanding the daily ingestion of the cod-liver oil which, during certain periods, averaged 5, 4, and 7 grams per kilogram of body weight of the respective animals. This result is in harmony with the indications of our curative trials and indicates that cod-liver oil contains little, if any, of the blacktongue preventive. It is in harmony also, it may be noted, with the results of the tests of this cod-liver oil in the human disease, so that cod-liver oil would seem to be poor in or lacking the preventive for both blacktongue and pellagra.

COTTONSEED OIL

The importance of cottonseed oil among the edible oils suggested the desirability of an inquiry into its blacktongue-preventive potency. The following experiment was accordingly carried out:

EXPERIMENT 14

The cottonseed oil [1] to be tested was incorporated in a diet, No. 302, the composition of which is shown in Table 12, and a suitable caloric portion of this was offered daily to each of six test animals, dogs 29, 50, 54, 110, 122, and 123. The significant details relating to each of the animals are as follows:

Dog 29.—Male. Acquired May 10, 1923. Has suffered several attacks of experimental blacktongue, the latest of which began September 17, 1927. On stock diet for reconditioning from September 27 to November 23, 1927.

November 23, 1927: In good condition; weighs 9.7 kilograms; begins test diet No. 302.

December 6: Weighs 10.2 kilograms. Has been eating well, regularly consuming the daily allowance of 1,000 grams of food, representing 46 grams of the cottonseed oil, or nearly 4.5 grams of the oil per kilogram of body weight.

December 9: Has continued to eat all food offered daily. Presents this morning, 17 days after starting the test, the first signs of an attack of blacktongue, a reddening of the mucosa of the floor of the mouth and of that of the upper lip on the left side. Progressive attack. Died December 19.

Dog 50.—Male. Acquired September 25, 1923. Up to May 25, 1927, served in various experiments and suffered several attacks of blacktongue, the latest of which began about May 8, 1927. On stock diet from May 25 to September 7, 1927.

September 7, 1927: In good condition; weighs 14.2 kilograms; begins test diet No. 302.

September 13: Weighs 14 kilograms. Daily food consumption since beginning the test diet has averaged approximately 740 grams, representing 34 grams of the cottonseed oil, or slightly short of 2.5 grams per kilogram of body weight.

[1] A commercial preparation marketed for domestic use under the name of Wesson Oil.

September 20: Weighs 14.2 kilograms. During the past week the daily food consumption has averaged approximately 850 grams, representing 39 grams of the oil, or fully 2.5 grams per kilogram of body weight.

September 27: Weighs 14 kilograms. Average daily food consumption during the past week has been approximately 880 grams representing 40 grams of the oil or a little over 2.5 grams per kilogram of body weight. Presents this morning, 20 days after beginning the test diet, the first signs of an attack of blacktongue, a sharply delimited red band on the mucosa of the upper lip of each side, reddening of the mucosa of the floor, cheeks, and fauces. Further history not relevant.

Dog 54.—Bitch. Acquired September 25, 1923. Up to September 7, 1927, served in several experiments and suffered a number of attacks of blacktongue, of which mild, evanescent evidence of the latest was present between August 4 and August 9, 1927. On stock diet from September 7 to October 12, 1927.

October 12, 1927: In good condition; weighs 9.7 kilograms; begins test diet No. 302.

October 18: Weighs 9.3 kilograms. Daily food consumption since beginning the test diet has averaged approximately 840 grams, representing 38 grams of the cottonseed oil or fully 4 grams per kilogram of body weight.

October 25: Weighs 9.6 kilograms. During the past week has regularly consumed the daily allowance of 900 grams of food, representing 41 grams of the oil, or fully 4 grams per kilogram of body weight.

November 8: Weighs 8.9 kilograms. Appetite much dulled during the past two weeks. Daily food consumption during this period has averaged approximately 380 grams, representing 22 grams of the oil or fully 2 grams per kilogram of body weight.

November 12: Presents this morning, 31 days after beginning the test, the first signs of an attack of blacktongue, a reddened patch of mucosa of the upper lip on each side and an injection of the floor of the mouth. Further history not relevant.

Dog 110.—Bitch. Acquired October 29, 1926. Up to September 7, 1927, served in one experiment but developed no evidence of blacktongue. On stock diet from September 7 to October 12, 1927.

October 12, 1927: In good condition; weighs 12.7 kilograms; begins test diet No. 302.

October 18: Weighs 12.6 kilograms. Since beginning the test diet daily food consumption has averaged approximately 940 grams, representing 43 grams of the oil, or a little short of 3.5 grams per kilogram of body weight.

October 25: Weighs 12.7 kilograms. During the past week has regularly consumed the daily allowance of 1,000 grams of food, representing 46 grams of the oil, or fully 3.5 grams per kilgoram of body weight.

November 1: Weighs 12.5 kilograms. Appetite has become somewhat dulled. Daily food consumption during the past week has averaged approximately 760 grams, representing 35 grams of the oil, or fully 2.5 grams per kilogram of body weight.

November 15: Weighs 12.3 kilograms. Daily food consumption during the past two weeks has averaged approximately 690 grams, representing 32 grams of the oil, or fully 2.5 grams per kilogram of body weight.

November 19: Presents this morning, 38 days after beginning the test, the first evidence of an attack of blacktongue, an injection of the floor of the mouth. Further history not relevant.

Dog 122.—Bitch. Acquired May 11, 1927. On stock diet to September 7, 1927.

September 7, 1927: In good condition; weighs 8.1 kilograms; begins test diet No. 302.

September 13: Weighs 7.9 kilograms. Daily food consumption since beginning of test has averaged approximately 720 grams, representing 33 grams of the oil, or fully 4 grams per kilogram of body weight.

September 20: Weighs 7.9 kilograms. Daily food consumption during the past week has averaged approximately 755 grams, representing 34 grams of the oil, or slightly over 4 grams per kilogram of body weight.

September 27: Weighs 7.9 kilograms. Daily food consumption during the past week has averaged approximately 720 grams of food, representing 33 grams of the oil, or fully 4 grams per kilogram of body weight. Presents this morning, 20 days after beginning the test, the first evidence of blacktongue, an injection of the floor of the mouth. Further history not relevant.

Dog 123.—Bitch. Acquired May 11, 1927. On our stock diet No. 156 up to September 7. Threw a litter of seven pups June 29, which were successfully nursed and were weaned in good condition on August 9.

September 7, 1927: In good condition; weighs 7.8 kilograms; begins test diet No. 302.

September 13: Weighs 7.5 kilograms. Daily food consumption since beginning the test has averaged approximately 800 grams, representing 37 grams of the oil, or but little short of 5 grams per kilogram of body weight.

September 20: Weighs 7.3 kilograms. Food consumption during the past week has averaged approximately 610 grams, representing 28 grams of the oil, or fully 3.5 grams per kilogram of body weight.

October 4: Weighs 6.9 kilograms. Appetite has been dulled. Food consumption during the past two weeks has averaged approximately 470 grams, representing 22 grams of the oil, or fully 3 grams per kilogram of body weight.

Presents this morning, 27 days since beginning the test, the first evidence of blacktongue, an injection of the mucosa of the floor of the mouth.

Result and conclusion.—As appears in the foregoing, the high levels of food consumption among the test animals represented a consumption of fully 2.5 grams of the cottonseed oil per kilogram of body weight in one of them (dog 50), fully 3.5 grams in two (dogs 110 and 123), fully 4 grams in two (dogs 54 and 122), and nearly 4.5 grams in one (dog 29). Notwithstanding this, however, all six of the dogs developed blacktongue, the first buccal signs of which appeared at the end of periods of from 17 to 38 days. It would seem, therefore, that the test diet was without appreciable preventive action and, thus, that the cottonseed oil contained little, if any, of the blacktongue preventive.

No specific study of the effectiveness of cottonseed oil in pellagra has been made. Judged on the basis of general experience it seems unlikely that this oil contains the pellagra preventive in significant amounts.

LEAN BEEF

Very early in our study of experimental blacktongue, occasion arose for testing the curative value of fresh beef muscle, a food that there was reason to believe contained (10) (11), and later was demonstrated to contain, a good supply of the pellagra preventive (1). Since then we have repeatedly used fresh beef as a therapeutic agent. Our experience has been consistently favorable. We shall not detail

any of this, however, preferring instead to present the results of two experiments in which the more convincing preventive test of this food was carried out.

EXPERIMENT 15

This was a test of the blacktongue preventive action of fresh lean beef. Fresh round steak was first carefully trimmed free of gristle, tendon and visible fat, run through a meat chopper, and then incorporated in diet No. 196, the composition of which is shown in Table 13. This diet is essentially our basic blacktongue-producing diet No. 123 (Table 1), the casein of which has been replaced by a quantity of fresh lean beef calculated to yield the same amount of protein as does the casein. Of this diet suitable caloric portions were daily offered to each of five test animals, dogs 42, 62, 68, 69, and 76. The significant details relating to each animal are briefly as follows:

Dog. 42.—Male. Acquired June 26, 1923. Up to June 24, 1924, served in several experiments and suffered three attacks of blacktongue, the latest of which began April 2, 1924. In a test of yeast from June 24, 1924, to May 26, 1925, without presenting any evidence of blacktongue.

May 26, 1925: In good condition. Weighs 11.7 kilograms. Begins test diet No. 196.

May 26, 1926: Has been on diet No. 196 for one year. Weighs 13 kilograms. Is now and has throughout the year been in good condition and without any recognizable indications of blacktongue.

Dog 62.—Male. Whelped in the laboratory November 4, 1923. Reared and maintained on stock diets until June 24, 1924. In a test of yeast from June 24, 1924, to May 26, 1925, during which presented transient evidence of blacktongue March 24, 1925.

May 26, 1925: In good condition. Weighs 7.9 kilograms. Begins diet No. 196.

May 26, 1926: Completes one year on diet No. 196. Weighs 8.8 kilograms. Has presented no indications of blacktongue at any time during the year.

Dog 68.—Bitch. Whelped in the laboratory November 25, 1923. Reared and maintained on stock diets until June 24, 1924. In a test of yeast from June 24, 1924, to May 26, 1925, during which presented evanescent indications of blacktongue September 27, 1924.

May 26, 1925: In good condition. Weighs 8.1 kilograms. Begins diet No. 196.

May 26, 1926: Completes one year on diet No. 196. Weighs 9.6 kilograms. Has presented no evidence of blacktongue during the year.

Dog 69.—Male. Whelped in the laboratory November 5, 1923. Reared and maintained on stock diets until June 24, 1924. In a test of yeast from June 24, 1924, to May 26, 1925, during which presented no evidence of blacktongue.

May 26, 1925: In good condition. Weighs 8.3 kilograms. Begins test diet No. 196.

May 26, 1926: Completes one year on diet No. 196 Weighs 9.1 kilograms. Has presented no evidence of blacktongue during the year.

Dog 76.—Male. Acquired June 9, 1924. In a test of yeast from June 24, 1924, to May 26, 1925, during which presented no evidence of blacktongue.

May 26, 1925: In good condition. Weighs 9.2 kilograms. Begins diet No. 196.

May 26, 1926: Completes a year on diet No. 196 without having presented any signs of blacktongue. Weighs 10.1 kilograms.

Result and conclusion.—It appears from the foregoing that none of the five test animals presented any recognizable evidence of blacktongue during the experimental period of one year. Clearly, the fresh lean beef furnished enough, and possibly more than enough, of the blacktongue preventive for the complete protection of these animals during the specified experimental observation period.

EXPERIMENT 16

This was also a test of the blacktongue-preventive action of lean beef, but differed from the preceding experiment, first, in that the lean beef was dried and, second, that during the second of the two feeding periods of which the experiment consisted, the dried beef was boiled for about one and one-half hours with certain of the other ingredients of the test diet. During the first feeding period diet No. 196A (Table 13) was used, and during the second, diet No. 196B (Table 13). These were identical diets excepting only that in No. 196A the dried beef was stirred into the cooked food, while in No. 196B the dried beef was cooked as already mentioned. These diets, like diet No. 196, were essentially our basic blacktongue-producing diet No. 123, the casein of which was completely replaced by lean beef which, in this instance, however, was first dried.

The dried beef was prepared by taking the fresh chopped beef of the preceding experiment and first drying it at room temperature under the electric fan, then grinding coarsely, and finally drying (for about 18 hours) in a current of warm air. Thus dried, it was finely ground and stored ready for use. Fresh batches were prepared from time to time as needed.

The test animals were five dogs, numbered 41, 89, 90, 98, and 99, to each of which the test diet was offered in suitable caloric portions. The significant details relating to each of the animals are as follows:

Dog 41.—Bitch. Whelped in the laboratory June 26, 1923. Up to March 11, 1926, served in several experiments and suffered three attacks of blacktongue, the latest of which began March 4, 1925. On stock diet from March 11 to March 30, 1926.

March 30, 1926: In good condition; weighs 10.9 kilograms; begins diet No. 196A.

October 28, 1926: In good condition. Weighs 10.8 kilograms. Diet changed to No. 196B, thus beginning the second period of the experiment.

April 6, 1927: Has been on the dried-beef diets fully one year, during which period has not presented any evidence of blacktongue. Had a mild attack of an infective stomatitis between March 10 and March 15.[1] Is in good condition. Weighs 10.6 kilograms. Experiment discontinued.

Dog 89.—Bitch. Whelped in the laboratory October 12, 1924. Up to March 11, 1926, served in one experiment, but suffered no blacktongue. On stock diet from March 11 to March 30, 1926.

[1] At this time we had an epidemic of this condition among our animals. Dogs in a number of different experiments then in progress were more or less severely attacked. The condition and its differentiation from blacktongue were briefly described in a previous communication (2).

March 30, 1926: In good condition; weighs 4.8 kilograms; begins diet No. 196A.

October 28, 1926: In good condition; weighs 4.7 kilograms; diet is changed to No. 196B.

April 6, 1927: About March 10 developed an infective stomatitis, since when there has been a very marked reduction in food consumption, with a great loss in weight. Weighs 2.8 kilograms. Has presented no recognizable evidence of blacktongue. Experiment is discontinued.

Dog 90.—Male. Whelped in the laboratory October 12, 1924. Up to March 11, 1926, served in one experiment, but did not develop blacktongue. On stock diet from March 11 to March 30, 1926.

March 30, 1926: In good condition; weighs 7.1 kilograms; begins test diet No. 196A.

October 28: In good condition; weighs 6.8 kilograms; diet is changed to No. 196B.

April 6, 1927: Developed a mild infective stomatitis about March 12, with which was associated a reduced food consumption; weighs 6.7 kilograms; is in good condition; has presented no evidence of blacktongue. Experiment is discontinued.

Dog 98.—Male. Acquired January 18, 1926, when about 9 weeks old, at which time weight was 1.6 kilograms. On stock diet until March 30, 1926.

March 30, 1926: In good condition; weighs 4.9 kilograms; begins diet No. 196A.

October 28: In good condition; weighs 6.2 kilograms; diet is changed to No. 196B.

April 6, 1927: Had evidence of a mild infective stomatitis between March 19 and March 25. Is in good condition; weighs 6.6 kilograms. Has presented no evidence of blacktongue. Experiment is discontinued.

Dog 99.—Male. Litter mate of dog 98. Acquired January 18, 1926, when about 9 weeks old, at which time weight was 2.8 kilograms. On stock diet until March 30, 1926.

March 30, 1926: In good condition; weighs 8 kilograms; begins diet No. 196A.

October 28: In good condition; weighs 11.7 kilograms; diet is changed to No. 196B.

February 12, 1927: Taken sick about two weeks ago. Has a bloody nasal discharge, a purulent ophthalmia, and a cough. The dog is gassed. At necropsy there are found patches of consolidation scattered through both lungs. Nature of the infection not determined. No recognizable evidence of blacktongue.

Results and conclusions.—None of the five-test animals presented any recognizable evidence of blacktongue during either dietary period which, together, extended over fully 1 year for four dogs and 10 months for the fifth dog. The latter animal acquired a complicating infection which led to its elimination about two months before the expiration of the year that would normally have constituted the experimental observation period.

Recalling that dogs on basic blacktongue-producing diet No. 123 may be expected to develop the disease at the end of a period only exceptionally longer than about 60 days, it would appear that both the dried beef as such (in diet No. 196A) and the dried beef after boiling one and one-half hours retain much, if not all, of the preventive potency of the fresh beef.

The results of the foregoing experiments with beef muscle clearly indicate that, in relation to the type of basic diet employed, the

quantity used was fully adequate for preventive purposes. How much less would serve equally well we have so far not attempted to determine. It is difficult, or impossible, therefore, to appraise the relative preventive potency of the lean beef; but since the minimum adequate preventive quantity would seem to be not more, and may possibly be somewhat less, than the quantity tested, it is clear that lean beef is a good, if not a rich, source of the blacktongue preventive just as it is of the pellagra preventive, as was noted above.

PORK LIVER

Our study of the blacktongue-preventive action of meat includes, in addition to the test of lean beef detailed in the preceding, one of pork liver which we present in the following experiment:

EXPERIMENT 17

This was a test of the blacktongue-preventive action of dried pork liver. Livers were secured fresh from a local abattoir. Since they were, as a rule, received at the laboratory late in the afternoon, they were stored over night in the laboratory refrigerator room. Next morning, after trimming them as free as possible of ligamentous tissue, they were run through the meat chopper. The livers thus minced were spread out in pans and kept under the electric fan at room temperature, with repeated stirring, until nearly dry. This required some 48–72 hours. They were then again run through the meat chopper, after which the drying was continued and completed in a current of warm air. This final drying took about 18 hours. The liver so dried was then finely ground and stored. Enough was prepared at the beginning of the experiment to supply our requirements during the first seven months of this study. The dried liver used during the last four months of the eleven-month experimental period was prepared in small batches about every two weeks and by a slightly different procedure. In this method the minced fresh livers were heated in a double boiler, without any addition of water, for about 15 minutes to, at least, partially coagulate the protein before being put under the fan to dry. This greatly expedited the drying at air temperature, the duration of which was reduced to some 24–36 hours. The other steps in the procedure were as already described. The dried liver was incorporated in a diet, No. 292, the composition of which is shown in Table 14. By comparison with dried beef diet No. 196B (Table 13), it may be seen that liver diet, No. 292, was essentially identical with this dried beef diet, except that the dried liver quantitatively replaced the dried beef. It may be noted as an additional point of similarity to diet No. 196B that in the preparation of diet No. 292 the dried liver was cooked for about 1½ hours with certain of the other ingredients. By reference to Table 1 it may be

seen further that the dried liver diet was essentially basic diet No. 123, the casein of which was almost completely replaced by dried liver.

Suitable portions of the liver diet were daily offered to each of five test animals, dogs 90, 95, 98, 117, and 118. The significant details relating to each are as follows:

Dog 90.—Male. Whelped in the laboratory October 12, 1924. Up to April 6, 1927, had served in two experiments but had no blacktongue. On stock diet from April 6 to May 12, 1927.

May 12, 1927: In good condition; weighs 7.2 kilograms; begins test diet No. 292.

April 10, 1928: In good condition; weighs 7.2 kilograms. Has presented no recognizable evidence of blacktongue at any time during the experimental period of 11 months.

Dog 95.—Acquired November 30, 1925. Has served in one experiment but has had no blacktongue. On stock diet from March 15 to May 12, 1927.

May 12, 1927: In good condition; weighs 8.2 kilograms; begins diet No. 292.

April 10, 1928: In good condition; weighs 9.1 kilograms. Has presented no recognizable evidence of blacktongue during the observation period of 11 months.

Dog 98.—Male. Acquired January 18, 1926. Has served in one experiment but has not had blacktongue. On stock diet from April 6 to May 12, 1927.

May 12, 1927: In good condition; weighs 6.5 kilograms; begins liver diet No. 292.

April 10, 1928: Weighs 7.1 kilograms; in good condition. Has presented no recognizable evidence of blacktongue at any time during the experimental period of 11 months.

Dog 117.—Bitch. Acquired April 9, 1927. On stock diet to May 12, 1927.

May 12, 1927: In good condition; weighs 7.8 kilograms; begins diet No. 292.

April 10, 1928: Appetite and food consumption have been consistently good throughout since the beginning of the experiment 11 months ago. Gained in weight during the first three months. Then during the succeeding seven months, that is, until about the end of February, 1928, the weight oscillated between 9 and 9.5 kilograms. Since early in March, although the food consumption has continued excellent, weight has slowly declined, reaching 8.5 kilograms on April 3. To-day weighs 9.3 kilograms, this gain being coincident with an increase in food allowance. About March 31 it was noted that there was a slight weakness in coordination in the hind legs which was chiefly noticeable in walking, especially on a wet slippery floor. This has persisted and is now seemingly more marked. The nature of this neurological condition, which seems identical with that of dog 119 of experiment 19, is not understood. Is lively and playful. Does not present and has not presented at any time during the period of 11 months any recognizable evidence of blacktongue.

Dog 118.—Bitch. Acquired April 9, 1927. On stock diet to May 12, 1927.

May 12, 1927: In good condition; weighs 7.8 kilograms.

April 10, 1928: Weighs 9.8 kilograms. Is in good condition. Has presented no recognizable evidence of blacktongue during the experimental period of 11 months.

Results and conclusions.—It appears from the foregoing that none of the five test dogs presented any recognizable signs of blacktongue during the experimental period of 11 months. Recalling that dogs fed basic diet No. 123 (Table 1) may be expected to develop black-

tongue within a period only exceptionally longer than about 60 days (2), and recalling further that test diet No. 292 differs from diet No. 123 essentially only in that dried pig's liver replaces nearly all of the casein of the latter diet, it clearly follows that the difference in the results of the feeding must be attributed to the liver. We may conclude, therefore, that dried and cooked pork liver contains the blacktongue preventive; and since the minimum preventive quantity would seem to be not more, and may be, or probably is, less, than that indicated by the quantity contained in diet No. 292, the liver may be considered as, at least, a good, if not rich, source of the blacktongue preventive. Liver has not, as yet, been studied by us in pellagra.

SALMON

In much of the rural area and in many of the isolated industrial communities of the southern part of the United States where pellagra is most prevalent, the fresh meat supply is very restricted or there is none at all from about the first of March until some time in October or November. During this period fresh meat is in some measure replaced by preserved meat of some kind, including fish. Among the preserved fish, canned salmon is perhaps the most conspicuous. We therefore thought it worth while to test the blacktongue preventive action of canned salmon, as is shown in the following:

EXPERIMENT 18

In this study of the blacktongue-preventive action of canned salmon we used a canned Alaska chum salmon. The chum salmon is one of the cheaper varieties and was chosen for study for that reason. The entire contents of the can (of 1 pound (454 grams) size), thus including skin and bone, were incorporated in a diet, No. 294, the composition of which is shown in Table 15. As may be seen by reference to Tables 1 and 13 this diet is very similar to basic diet No. 123 and to beef-containing diet No. 196. The amount of salmon included (300 grams per 2,400 calorie ration) was largely arbitrary, although in part influenced by the quantity of lean beef included in diet No. 196. Suitable portions of this diet were offered daily to each of five test animals, dogs 60, 64, 73, 89, and 120. The significant details relating to each are briefly as follows:

Dog 60.—Male. Whelped in the laboratory November 4, 1923. Has suffered several attacks of blacktongue, the latest of which, very evanescent and doubtful, was in evidence June 7, 1926 On stock diet from March 15 to May 27, 1927.

May 27, 1927: In good condition; weighs 8.2 kilograms; begins salmon test diet No. 294.

April 17, 1928: In good condition; weighs 8.6 kilograms; has at no time during the experimental period of ten and a half months presented any recognizable evidence of blacktongue.

Dog 64.—Bitch. Whelped in the laboratory November 4, 1923; has suffered several attacks of blacktongue, the latest of which, evanescent and uncertain, was in evidence September 29, 1926; on stock diet from March 15 to May 27, 1927.

May 27, 1927: In good condition; weighs 7.6 kilograms; begins test diet No. 294.

April 17, 1928: In good condition; weighs 7.8 kilograms; has at no time during the experimental period of ten and a half months presented any recognizable evidence of blacktongue.

Dog 73.—Bitch. Acquired March 19, 1924; has suffered several more or less marked attacks of blacktongue, the latest of which began December 17, 1925; on stock diet from March 15 to May 27, 1927.

May 27, 1927: In good condition; weighs 10.5 kilograms; begins test diet No. 294.

April 17, 1928: In good condition; weighs 11 kilograms; has at no time during the experimental period of ten and a half months presented any recognizable evidence of blacktongue.

Dog 89.—Bitch. Whelped in the laboratory October 12, 1921; has served in two experiments without developing blacktongue; on stock diet from April 6 to May 27, 1927.

May 27, 1927: In good condition; weighs 4.1 kilograms.

April 17, 1928: In good condition; weighs 4.8 kilograms; has presented no recognizable evidence of blacktongue at any time during the experimental period of ten and a half months.

Dog 120.—Bitch. Acquired April 9, 1927; on stock diet to May 27.

May 27, 1927: In good condition; weighs 7.1 kilograms; begins test diet No. 294.

April 17, 1928: In good condition; weighs 9.5 kilograms; has presented no recognizable evidence of blacktongue at any time during the experimental period of ten and a half months.

Results and conclusions.—As is evident from the foregoing, none of the five test animals presented any recognizable evidence of blacktongue during the experimental period of 10½ months. Clearly the test diet exercised complete preventive action. It may therefore be concluded that canned chum salmon contains the blacktongue preventive. The quantity of salmon in the test diet would appear to be a liberal one. How much less might have been equally effective can not be stated.

A comparable study of salmon in pellagra is under way, but is not sufficiently advanced to justify the expression of any judgment as to the outcome.

EGG YOLK

The importance of the hen's egg in the human diet, especially in the diet of children and invalids, and the possibility of its availability under climatic and other conditions which would restrict or make impracticable the supply of fresh meat, suggested the desirability of a test of its blacktongue-preventive action. As the yolk is the portion generally considered to contain the vitamins of the egg, we decided to work with the yolk, and for reasons of practical convenience decided to work with the dried yolk.

We began the study with a commercial preparation of dried, powdered egg yolk, of which we incorporated 100 grams in a 2,400-

caloric ration. As two of the five dogs to which such diet was fed developed blacktongue at the end of 42 and 52 days, respectively, and since we knew nothing of the history of this dried yolk, it was deemed desirable to replace the commercial product with one freshly prepared by ourselves. Accordingly the experiment with the commercial dried yolk was discontinued and the dogs were put on stock diet for reconditioning. Following this the study was resumed and the following experiment was carried out:

EXPERIMENT 19

This was a test of the blacktongue-preventive action of dried egg yolk. Market eggs of excellent quality were boiled hard. The yolks were then separated from the white and run through the meat chopper, after which they were spread out in pans and dried under the fan at room temperature for about 18 hours. The drying was then continued and completed in a current of warm air during an additional period of about 24 hours. So dried, and coarsely ground, the yolks were stored ready for use. Fresh batches were prepared about every two weeks.

The dried egg yolk was incorporated in the diet, No. 293B, shown in Table 16. Except for the character of the dried yolk this diet, it may be remarked, is identical with that in which the commercial powdered egg yolk was tested. It contains, as Table 16 shows, 100 grams of our dried yolk, corresponding to the yolks of about 12 average eggs, in each 2,400 calorie ration. Suitable portions of this diet were daily offered to each of five animals, dogs 41, 63, 67, 70, and 119. The significant details relating to each are as follows:

Dog 41.—Bitch. Whelped in the laboratory June 26, 1923. Up to April 6, 1927, had suffered three attacks of blacktongue, of which the latest began March 4, 1925. On stock diet from April 6 to May 12, 1927. On a commercial dried egg yolk diet from May 12 to June 30, 1927. On stock diet from June 30 to August 2, 1927.

August 2, 1927: In good condition; weighs 11.7 kilograms; begins dried egg yolk test diet No. 293B.

On October 31, or at end of a period of 90 days, presented a suggestive reddening of the mucosa of the floor of the mouth, which was more pronounced next day and then gradually faded so that it was no longer recognizable on November 5, 1927.

April 10, 1928: Has presented no recognizable evidence of blacktongue since the transient indications present between October 31 and November 5, 1927. Weighs 10.7 kilograms. Appears in good condition.

Dog 63.—Male. Whelped in the laboratory November 4, 1923. Has served in several experiments and has suffered several attacks of blacktongue, the latest of which began June 28, 1927, while on a commercial dried egg yolk diet. On stock diet from June 30 to August 2, 1927.

August 2, 1927: In good condition; weighs 9 kilograms; begins test diet No. 293B.

On October 28, or at the end of a period of 87 days, presented the first signs of an attack of blacktongue, a sharply limited bilaterally symmetrical erythema in

bandlike form on mucosa of the upper lip, a reddening of the mucosa of the floor of the mouth and of the cheeks and faucial pillars. Attack became progressively more pronounced necessitating the withdrawal of this animal from the experiment on November 1. Further history not relevant.

Dog 67.—Male. Whelped in the laboratory November 25, 1923. Presented suggestive but evanescent evidence of blacktongue January 13, 1927. Suffered a definite attack of blacktongue, which began June 23, 1927, while on a commercial dried egg yolk diet. On stock diet from June 30 to August 2, 1927.

August 2, 1927: In good condition; weighs 9.9 kilograms; begins test diet No. 293B.

On November 29 presented a suggestive reddening of the floor of the mouth which was no longer perceptible two days later.

On February 9, 1928, presented some very suggestive erythematous patches on the mucosa of the upper lip, which were no longer perceptible on February 11.

On March 6 presented evanescent but very suggestive erythematous patches on the mucosa of the upper lip and a reddening of the mucosa of the floor of the mouth.

On March 20, at the end of a period of 231 days, presented definite beginning signs of an attack of blacktongue, bilaterally symmetrical erythematous bands on the mucosa of the upper lip, reddening of the mucosa of the floor, cheeks, and faucial pillars. This slowly progressed and became so grave by April 5 that treatment was begun, but the attack ended in death April 7–8, 1928.

Dog 70.—Male. Whelped in the laboratory November 25, 1923. Has presented several attacks of blacktongue, the latest indications of which were in evidence August 10, 1926. On a commercial dried egg yolk diet from May 12 to June 30, 1927. On stock diet from June 30 to August 2, 1927.

August 2, 1927: In good condition; weighs 10.3 kilograms; begins egg yolk diet No. 293B.

April 10, 1928: Weighs 9 6 kilograms; in good condition. Has presented no recognizable evidence of blacktongue at any time during the experimental period of eight months

Dog 119.—Bitch. Acquired April 9, 1927. On a commercial dried egg yolk diet from May 12 to June 30, 1927. On stock diet June 30 to August 2, 1927.

August 2, 1927: In good condition; weighs 8.2 kilograms; begins diet No. 293B.

April 10, 1928: About March 22 there was noted as present a weakness or incoordination in the movements of the hind limbs and a slightly high-stepping action of the forelegs, which have persisted. The nature of this neurological manifestation is not clear. Weighs 8 9 kilograms. Seems lively and playful. Has presented no recognizable indications of blacktongue.

Results and conclusions.—As appears in the foregoing, two of the test animals (dogs 63 and 67) developed definite attacks at the end of 87 and 231 days, respectively, while a third presented very suggestive but transient indications of blacktongue. The remaining two of the five test animals presented no recognizable evidence of the disease during the experimental period of fully eight months.

This result indicates quite clearly that the dried egg yolk in the test diet had not exercised adequate blacktongue preventive action. A delaying or partially protective action seems, however, to be definitely suggested, thus indicating that egg yolk contains the blacktongue preventive but, at least when dried and cooked, in relatively

small amount. Although there appears to be no good reason to believe that the drying and cooking to which the yolk was subjected would be likely appreciably to affect the blacktongue preventive contained therein, nevertheless, until this possibility can be definitely excluded, no final conclusion as to the relative richness of the yolk in the blacktongue preventive is warranted by the results of the foregoing experiment. It seems permissible, nevertheless, to suggest in a tentative way that, if, as seems on the whole probable, the potency of the egg yolk is not materially diminished by drying, the cooked yolk, as such, is, gram for gram, inferior in blacktongue preventive potency to fresh beef, pork liver, and wheat germ.

Egg yolk has not yet been tested by us as to its preventive value in human pellagra.

TOMATOES

It may be recalled that the diet used by Goldberger and Wheeler in the first experiment which resulted in the production of blacktongue (2) included tomato juice as one of the components. Tomato juice was, therefore, subsequently included in several experimental diets under the impression that it was without appreciable blacktongue-preventive action. In connection with one such diet, however, in which an amount of juice larger than ordinary was included in order to insure an abundance of "vitamin B," the attacks of blacktongue were so much delayed in their appearance as to suggest that, as in the case of yeast (3), we may not have taken sufficient account of the possibilities of the factor of quantity. This suggested the desirability of a more specific inquiry into the blacktongue-preventive potency of the tomato. Together with certain other considerations it also suggested the desirability of a similar inquiry into its pellagra-preventive potency. A test of the latter was, accordingly, carried out at the Georgia State Sanitarium by Goldberger and Wheeler (13), who, as a result, found that when the daily quantity is sufficiently liberal, the pellagra-preventive action of tomatoes becomes unmistakable. As will be seen, the results of our studies in the dog, presented in the following experiments, lead to the same conclusion with respect to their blacktongue-preventive action.

EXPERIMENT 20

This was a test of the curative and the preventive action of tomatoes, or, more precisely, of the juice pressed from canned tomatoes. The tomatoes were a commercial product of good quality in cans containing about 1 kilogram. The contents of the required number of cans were thrown on a cloth and, in this, hand pressed, and the juice was collected for use. This was done daily. A measured amount—at first about 12 c. c., later increased to 20 c. c., and finally to about 30 c. c. per kilogram of body weight—was daily

administered by drench, using a convenient metal syringe, as a supplement to basic blacktongue producing diet No. 123. (Table 1.) The test animals were five dogs, numbered 13, 50, 66, 81, and 82. Four of these (dogs 50, 66, 81, and 82) were each in the early stage of an attack of blacktongue when the test was begun. The significant details relating to each of the animals are as follows:

Dog 13.—Male. Acquired April 7, 1923. Up to January 18, 1925, served in several experiments and suffered six attacks of blacktongue, of which the latest began January 6, 1925. On stock diet from January 18 to February 18, 1925.

February 18, 1925: In good condition. Weighs 11.2 kilograms. Begins basic blacktongue-producing diet No. 123 with a daily supplement of 132 c. c., or about 12 c. c. per kilogram of body weight, of tomato juice by drench.

September 12: Weighs 10.3 kilograms. Appetite has been dull and food consumption has been on a reduced level. On July 31, presented evanescent signs suggestive of blacktongue. The daily dose of tomato juice is this day increased to 210 c. c., or about 20 c. c. per kilogram of body weight.

March 13, 1926: Weighs 9.7 kilograms. Has presented no definite signs of blacktongue since the suggestive evanescent indications that were present on July 31, 1925. Since some of the other test animals have developed blacktongue, however, an increase in the daily dose to 315 c. c., or about 30 c. c. per kilogram of body weight, is made to-day.

November 17, 1926: Weighs 9.3 kilograms. Has presented no recognizable evidence of blacktongue in over a year. Experiment is discontinued.

Dog 50.—Male. Acquired September 25, 1923. Up to June 23, 1925, served in various experiments and suffered several attacks of blacktongue, the latest of which began June 14, 1925.

June 23, 1925. Had been on basic diet No. 123 for some time and now has an attack of blacktongue, which began June 14. Weighs 12.1 kilograms. Begins treatment with a daily dose of 144 c. c., or 12 c. c. per kilogram of body weight, of tomato juice as a supplement to diet No. 123, which continues to be offered.

September 12: Mouth lesions cleared up promptly. Presented a scrotal lesion of uncertain significance early in July. Weighs 12 kilograms. The daily dose of tomato juice is this day increased to 240 c. c., or 20 c. c. per kilogram of body weight.

March 13, 1926: Presented transient signs suggestive of blacktongue September 17 and November 11, 1925, and January 9, February 16, and March 7, 1926. It is deemed desirable, therefore, to increase the dose of tomato juice to 345 c. c., or about 30 c. c. per kilogram of body weight, effective to-day. Weighs 11.2 kilograms.

March 15, 1927: Weighs 12 kilograms. Presented evanescent signs of blacktongue on March 16, 1926, but has presented none since that date. In good condition. Experiment is discontinued.

Dog 66.—Male. Whelped in the laboratory November 25, 1923. Reared on stock diets. Between April 22, 1924, and June 19, 1925, served in two experiments and suffered an attack of blacktongue, a relapse of which began June 11, 1925.

June 19, 1925: The signs of blacktongue first noted June 11 have become well marked. Began treatment with a daily dose of 132 c. c., or about 12 c. c. per kilogram of body weight, of tomato juice yesterday and begins basic diet No. 123 to-day. Weighs 10.5 kilograms.

September 12: The buccal lesions of blacktongue present when treatment began gradually improved and by the end of June the mouth was about normal. Transient signs of blacktongue were again in evidence, however, on August 22

and August 25. Buccal lesions reappeared September 9; have persisted and are more pronounced to-day. It is decided, therefore, to increase the dose of tomato juice to 230 c. c., or to about 20 c. c. per kilogram of body weight, effective to-day. Diet No. 123 has continued to be offered. Weight four days ago was 11.5 kilograms.

December 17: The signs of blacktongue have several times faded only to reappear —that is, the attack has taken on a chronic relapsing form characterized by marked weakness in the hind legs. The general condition of the animal has been on a decline. Weighs 8.2 kilograms. The tomato-juice treatment is this day supplemented with autoclaved yeast, the administration of which is begun in a dose of 23 grams in gelatine capsules.

January 20, 1926: Weighs 9.6 kilograms. Condition has greatly improved. Signs of blacktongue have cleared up. The autoclaved yeast, which has been given daily, is discontinued. The daily dose of tomato juice is this day increased to 345 c. c., or to about 30 c. c. per kilogram of normal body weight.

December 3, 1926: Presented an evanescent but suggestive injection of the floor of the mouth February 12 and again on May 12. This morning presents very suggestive buccal lesions. During May and June presented a very suggestive desquamative lesion of the scrotum. Three days ago weighed 9.8 kilograms.

January 8, 1927: Buccal lesions noted a month ago gradually faded out. Suggestive reddened lesions on mucosa of upper lip and an injection of the floor are present this morning. A weakness in hind legs similar to that from which he had practically recovered on the yeast treatment has been developing for about a week. The animal walks with difficulty. In walking, the hind legs are spread out so much that the pelvis barely clears the floor. Four days ago weighed 7.9 kilograms. General nutrition poor; eating poorly.

January 18: Condition becoming more unfavorable. Buccal mucosa is pale. Flaccid paraplegia is, if anything, more pronounced. Emaciated. As a whole this animal would seem to be suffering from a chronic blacktongue complicated by self-imposed semistarvation. Gassed. Tissues taken by Dr. James Denton for histopathological study. The chronicity of the disease extending over a period of a year suggests a partially protective action of the tomato juice.

Dog 81.—Male. Acquired October 13, 1924. On stock diet to November 21, 1924.

December 27, 1924: Has been on basic diet No. 123 since November 21 and this morning presents the first signs of an attack of blacktongue, an injection of the mucosa of the floor of the mouth and of the cheeks. Weighs 10.4 kilograms. Begins treatment with tomato juice in a daily dose of 126 c. c., or about 12 c. c. per kilogram of body weight, as a supplement to diet No. 123.

January 2, 1925: Signs of blacktongue have faded. Buccal mucosa is about normal.

April 10: An evanescent reddening of the floor of the mouth was observed on January 23. Not again observed until three days ago, since when it has become more pronounced and definite. The daily dose of tomato juice is, therefore, increased, this day to 189 c. c., or about 18 c. c. per kilogram of body weight. Weighs 11.1 kilograms.

April 13: Mouth appears normal this morning.

November 7: Early in August there appeared a desquamative dermatitis of the scrotum which, ill defined at first, gradually developed more distinctive characters. It has persisted, undergoing repeated changes in intensity. Since August 22, suggestive but transient buccal lesions have number of times appeared and each time faded. They have latterly tended to become more pronounced and definite. Food consumption has been much reduced recently.

Four days ago weighed 9.7 kilograms. Died suddenly this forenoon as the result of a gastric hemorrhage.

The mild relapsing course over a period of some 10 months suggests a delaying of partially protective action of the tomato juice.

Dog 82.—Bitch. Acquired October 13, 1924. On stock diet to November 21, 1924.

December 23, 1924: Has been on basic diet No. 123 since November 21, 1924, and this morning presents the first signs of an attack of blacktongue, reddened lesions on the mucosa of the upper lip, reddening of the mucosa of the floor of the mouth and of the cheeks. Weighs 11.5 kilograms. Begins treatment with tomato juice in a daily dose of 140 c. c., or about 12 c. c. per kilogram of body weight, as a supplement to diet No. 123.

December 27: The attack of blacktongue has become more pronounced. The temperature this morning is 40°. More potent therapy being indicated, the dog is given 23 grams of brewery yeast in capsules in place of the tomato juice.

January 3, 1925: Condition has improved markedly. Mouth is nearly normal. Has received a daily dose of 23 grams of yeast. This is discontinued and the treatment with a daily dose of 140 c. c. of tomato juice is resumed.

March 8: Presents this morning reddened patches on the mucosa of the upper lip and some injection of the floor of the mouth. Weighs 12.7 kilograms.

March 12: Buccal lesions have faded.

April 7. Floor of mouth is suggestively reddened.

April 8: Mouth appears normal.

April 16: Mucosa of cheeks and of floor of mouth suggestively reddened.

April 19: Mouth again normal.

April 28: Mucosa of cheeks and of floor of mouth suggestively reddened.

April 29: Buccal lesions have faded.

September 12: The daily dose of tomato juice is made 280 c. c., or about 20 c. c. per kilogram of body weight. Weighs 14 kilograms

March 13, 1926: Has presented no evidence of blacktongue in nearly a year. The dose of tomato juice is nevertheless increased to 420 c. c., or to about 30 c.c. per kilogram of body weight. Weighs 13 kilograms.

November 17: Since last April has a number of times passed tarry-looking bowel evacuations. Has been eating well. Weighs 14.5 kilograms. Has presented no recognizable evidence of blacktongue since April 29, 1925—that is, during about 18½ months. Experiment is discontinued.

Results and conclusions.—From the foregoing it appears that the dose of tomato juice (about 12 c. c. per kilogram of body weight) tried at the outset was inadequate both in treatment and prevention. But later, following the use of larger doses (20 to 30 c. c. per kilogram) a very definite preventive effect became appreciable (dogs 13, 50, 82), but this was not fully adequate for two of the animals (dogs 66, 81). It may be concluded, therefore, that tomatoes possess blacktongue-preventive action, but that this is of a feeble order, upward of 30 c. c. per kilogram of body weight (of the canned tomato juice) may be needed for complete protection when used as a supplement to such diet as our No. 123 (Table 1). This result is thus in close agreement with the experience of Goldberger and Wheeler, cited in the foregoing, in the human disease. The canned tomato, therefore, contains the preventive for both blacktongue and pellagra, but, considering quantity, contains it in relatively small amount.

CARROTS

As a result of their study of the Chittenden-Underhill syndrome in dogs, Underhill and Mendel (6) reported in May, 1925, that they had found carrots particularly effective in alleviating that syndrome when it was once initiated. Since it had already been suggested (12) that the Chittenden-Underhill syndrome in dogs was probably identical with blacktongue, it seemed desirable to test the efficacy of carrots in the experimental condition with which we were working and which we identified as blacktongue. The following experiment was accordingly carried out.

It may be noted that concurrently with this study in dogs, Goldberger and Wheeler (13) carried out a study of carrots in the human disease and found that the ingestion of the cooked equivalent of some 400 to 450 grams of this vegetable daily was inadequate to prevent pellagra in insane pellagrins weighing 46 to 63 kilograms; the attacks appeared after somewhat longer periods than their experience had led them to expect, thus suggesting a delaying or slightly protective effect of which, however, they could not be sure.

EXPERIMENT 21

This was a test of the curative and the preventive action of carrots in experimental blacktongue. The test animals were five dogs, Nos. 44, 60, 63, 64, and 70. The experiment was begun as a therapeutic study, each one of the animals presenting more or less marked buccal signs of an early stage of the experimental disease. This phase of the experiment lasted about two months and was followed by a period of about one month of reconditioning on stock diet. The preventive test started immediately after this reconditioning period.

The carrots were dressed as for human consumption, run through a meat-chopping machine, and then, with the smallest practicable amount of water, cooked for about two hours in a double boiler. Thus prepared and tender they were offered daily to each animal in definite weighed amounts apart from the basic blacktongue-producing diet. In the later stage of the study a small amount of the basic diet was mixed with the carrots ration of each animal. As a rule, the carrots were offered to the dogs before noon of each day. What was found uneaten a few hours later was forcibly fed. A small, negligible amount was unavoidably wasted in connection with this forced feeding.

The therapeutic dose with which the study was begun represented 180 grams of the raw dressed vegetable per dog per day. As the animals were not of uniform weight, the dose in relation to weight varied from about 15 to 25 grams per kilogram. This was increased

to 270 grams, or from about 25 to 40 grams per kilogram of body weight, during about the last two weeks of this phase of the study.

The preventive dose begun with was the equivalent of 300 grams of raw dressed carrots per dog per day, or from about 25 to 40 grams per kilogram of body weight. After a period of three months this was increased to 600 grams per dog per day, or to about 50 to 85 grams per kilogram of body weight.

The basic diet used during the first period was our blacktongue producing diet No. 209 on which, indeed, four of the test animals (dogs 44, 60, 63, and 64) had developed the attacks for which they were given the carrots by way of treatment. The fifth dog had developed the attack on another diet, but was given diet No. 209 when treatment with carrots was begun Diet No. 209 is our diet No. 123 (Table 1), the white corn meal of which was quantitatively replaced by yellow meal (3). During the preventive period of the test, basic diet No. 123 was used. The significant details are briefly as follows:

Dog 44.—Male. Whelped in the laboratory June 26, 1923. Served in several experiments and suffered three attacks of blacktongue, of which the latest began September 1, 1925, while on test diet No. 209.

September 15: The attack of blacktongue, the first signs of which appeared September 1, is now well defined but still mild. Weighs 12.1 kilograms. Continues on diet No. 209 and begins treatment with cooked carrots, the equivalent of 180 grams of the raw dressed vegetable, or about 15 grams per kilogram of body weight per day.

November 4: Weighs 11 3 kilograms. The mouth lesions present September 15 slowly faded, but almost at once began to reappear and have gradually become well defined and characteristic. The daily allowance of carrots is therefore increased effective to-day to the equivalent of 270 grams, or about 25 grams per kilogram of body weight, of the raw vegetable.

November 19: No beneficial effect being appreciable, the administration of carrots and basic diet No. 209 are discontinued and stock diet for reconditioning is begun. Weighs 11.4 kilograms.

December 17: All evidence of blacktongue rapidly cleared up following inauguration of the stock diet. Weighs 11.9 kilograms. In good condition. Begins basic diet No. 123 with a supplement of cooked carrots, representing 300 grams, or about 25 grams per kilogram of body weight, of the raw vegetable.

March 16, 1926: Slight but very suggestive indications of blacktongue appeared February 4. They soon faded, but have several times since then alternately reappeared and faded. Although not in evidence to-day, it is deemed desirable nevertheless to increase the daily supplement of carrots to the equivalent of 600 grams, or about 50 grams per kilogram of body weight, of the raw dressed vegetable. Weighs 12.6 kilograms.

March 15, 1927: On May 13, 1926, presented a slight but suggestive erythema of the scrotum which gradually faded and was entirely gone three days later. Has presented no buccal evidence of blacktongue in fully a year. Weighs 11.4 kilograms. Experiment is discontinued.

Dog. 60.—Male. Whelped in the laboratory November 4, 1923. Served in several experiments and has suffered two attacks of blacktongue, the latest of which began September 13, 1925, while on test diet No. 209.

September 15, 1925: The buccal lesions of the attack, the first signs of which appeared two days ago, are mild but definite this morning. Weighs 7.4 kilograms. Begins treatment with boiled carrots, of which the equivalent of 180 grams, or about 25 grams per kilogram of body weight, of the raw dressed vegetable is to be administered daily.

November 6: The mouth lesions present when feeding of carrots began faded and were no longer recognizable five days later. A suggestive evanescent injection of the floor of the mouth was present October 3. Weighs 7.4 kilograms. The daily dose of carrots is this day increased to the equivalent of 270 grams, or about 35 grams per kilogram of body weight, of the raw dressed vegetable.

November 19: Suggestive buccal signs of blacktongue appeared two days ago. They are still faintly perceptible this morning. Begins stock diet for reconditioning.

December 17: Two days after the change to the stock diet all mouth signs were gone. General condition has improved. Weighs 8.1 kilograms. Resumes the test of carrots by beginning basic diet No. 123 with a daily supplement of cooked carrots equivalent to 300 grams, or about 35 grams per kilogram of body weight, of the raw dressed vegetable.

March 16, 1926: During the past two or three weeks has repeatedly presented slight, evanescent and more or less strongly suggestive buccal signs of blacktongue. Still presents some injection of the floor of the mouth which appeared three days ago. Weighs 7 5 kilograms.

The daily allowance of boiled carrots is this day increased to the equivalent of 600 grams, or about 70–80 grams per kilogram of body weight, of the raw dressed vegetable.

April 28: The mouth lesions present on March 16 faded in the course of the succeeding two or three days, but have alternately reappeared and faded two or three times since. Mouth is normal this morning. Weighs 7 kilograms.

May 26: A marginated scrotal dermal lesion began to develop about May 1. It gradually increased in extent and became desquamative. It has alternately paled and brightened a number of times, and then gradually cleared up so that the scrotum is well-nigh normal this morning. Buccal lesions of blacktongue reappeared May 13 and gradually became quite pronounced, but have practically completely faded. Weighs 7 kilograms.

June 7: Floor of mouth presents a suspicious injection.

June 9, 1926: Mouth is about normal.

May 15, 1927: Has presented no evidence of blacktongue since early last June, that is, during a period of about nine months. Weighs 7.5 kilograms. Experiment is discontinued.

Dog 63.—Male. Whelped in the laboratory November 4, 1923. Has served in several experiments and has suffered three attacks of blacktongue, the latest of which began August 29, 1925, while on test diet No. 209.

September 15, 1925: The attack of blacktongue, the first signs of which appeared August 29, has become definitely marked, but is still mild. Weighs 6.8 kilograms. Diet No. 209 is continued. Begins treatment with boiled carrots in a daily dose representing 180 grams, or about 25 grams per kilogram of body weight, of the raw dressed vegetable.

November 6: The buccal signs of blacktongue have alternately faded and reappeared a number of times since the treatment with carrots was begun. Weighs 7.2 kilograms. The dose of boiled carrots is this day increased to an equivalent of 270 grams, or about 35 grams per kilogram of body weight, of the raw vegetable.

November 19: In spite of the increased dose of carrots the buccal lesions of blacktongue have become more severe. Temperature was 40° yesterday and

is 39.9° this morning. Diet No. 209 and carrots are discontinued and stock diet is begun. Two days ago weighed 6.5 kilograms. Eating poorly.

November 21: The condition of the animal seeming to be grave, it was given a dose of 7 grams of a dried yeast extract yesterday and another today. Refused all food yesterday.

December 7: Condition has rapidly improved. Appetite returned a day or two after the second dose of the yeast extract and has been eating well since.

December 17: In good condition. Weighs 7.1 kilograms. Begins diet No. 123 with a daily supplement of the coooked equivalent of 300 grams, or about 40 grams per kilogram of body weight, of raw dressed carrots.

January 23, 1926: Presents this morning strongly suggestive buccal sings of blacktongue.

March 16: The mouth lesions noted January 23 became more pronounced, then faded only to reappear and are appreciable this morning. It is deemed desirable, therefore, to increase the allowance of carrots. Effective to-day the cooked equivalent of 600 grams, or about 80 grams per kilogram of body weight, of raw dressed carrots is offered and is to be offered daily.

June 27: The mild buccal lesions present on March 16, when the allowance of carrots was increased, gradually faded but soon reappeared only to fade again. This alternate appearance and disappearance has been two or three times noted; the latest appearance of a slight injection of the floor of the mouth was yesterday but is not appreciable this morning. A very strongly suggestive dermal scrotal lesion made its appearance on May 12 but had cleared up by May 25. Weighs 6.6 kilograms.

May 15, 1927: During the past 8½ months there has been no evidence suggestive of blacktongue. Weighs 7.6 kilograms. Experiment is discontinued.

Dog 64.—Bitch. Whelped in the laboratory November 4, 1923. Has suffered two attacks of blacktongue, the latest of which began September 12, 1925, while on test diet No. 209.

September 15, 1925: Slight buccal signs of the attack which began three days ago are in evidence. Weighs 6.8 kilograms. Continues diet No. 209 and begins treatment with cooked carrots in a daily dose equivalent to 180 grams, or about 25 grams per kilogram of body weight, of the raw vegetable.

November 6: The mouth lesions present when treatment was begun faded and were no longer appreciable five days later. On October 20 a suggestive injection of the floor of the mouth was again in evidence, but faded during the succeeding three days. Weighs 6.6 kilograms. The daily allowance of boiled carrots is this day increased to the equivalent of 270 grams, or about 40 grams per kilogram of body weight, of the raw dressed vegetable.

November 19: Strongly suggestive mouth lesions reappeared two days ago and continue in evidence this morning. Diet No. 209 and treatment with carrots discontinued and stock diet is begun for reconditioning.

December 17: Mouth has been normal in appearance since November 21. In good condition. Weighs 7.2 kilograms. Begins diet No. 123 with a daily supplement of boiled carrots equivalent to 300 grams, or about 40 grams per kilogram of body weight, of the raw dressed vegetable.

March 16, 1926: Presented a suggestive injection of the floor of the mouth on February 20, which had largely faded by February 23. It was again in evidence for two or three days beginning March 2 and reappeared three days ago, but has completely faded. Weighs 6.2 kilograms. The daily allowance of boiled carrots is to-day increased to the equivalent of 600 grams, or about 85 grams per kilogram of body weight, of the raw vegetable.

October 1: Presented a suggestive injection of the mucosa of the floor of the mouth on March 21, which faded in three or four days. Has been free of any

suggestion of blacktongue until two days ago (about six months) when a suggestive reddening of the floor of the mouth was in evidence but is no longer appreciable. Weighs 7 kilograms.

March 15, 1927: There has been no suggestion of blacktongue since the evanescent injection of the floor of the mouth in evidence September 29, 1926—five and a half months ago. Weighs 7.3 kilograms. In good condition. Experiment discontinued.

Dog 70.—Male. Whelped in the laboratory November 25, 1923. Has served in several experiments and has suffered two attacks of blacktongue, the latest of which began September 15, 1925, while on wheat germ diet No. 197.

September 18, 1925: Three days ago weighed 9.6 kilograms. The attack of blacktongue, the first signs of which appeared three days ago, is now well marked. Begins diet No. 209 with a supplement of boiled carrots equivalent to 280 grams, or about 30 grams per kilogram of body weight, of the raw dressed vegetable.

September 28: The mouth lesions became quite severe, but have shown a marked improvement during the past three or four days. Has taken none of the basic diet since September 21, but a little of it was mixed with the boiled carrots yesterday and so forcibly fed. Weighs 7.8 kilograms. Beginning to-day the daily dose of boiled carrots will be the equivalent of 180 grams, or about 20 grams per kilogram of body weight, of the raw vegetable.

October 7: The mouth is now about normal in appearance.

November 19: Buccal lesions suggestive of blacktongue reappeared about two weeks ago and have gradually become more definite. Weighs 9.2 kilograms. Diet No. 209 and carrots discontinued and stock diet for reconditioning begins.

December 17: Weighs 9.4 kilograms. Is in good condition. Begins diet No. 123 with a daily supplement of boiled carrots—the equivalent of 300 grams, or about 30 grams per kilogram of body weight, of the raw dressed vegetable.

March 16, 1926: Has presented evanescent, but suggestive, buccal signs of blacktongue which were in evidence on February 4 and again three days ago and which are more definite to-day. Weighs 10.2 kilograms. The allowance of boiled carrots is this day increased to the equivalent of 600 grams, or about 60 grams per kilogram of body weight, of the raw vegetable.

March 18: Mouth is about normal again.

June 10: Slight but suggestive buccal lesions appeared a week ago but are no longer appreciable.

June 19: Some suggestive injection of the floor of the mouth reappeared a week ago but is no longer recognizable.

July 7: A suggestive injection of the floor of the mouth appeared July 1, but has faded.

July 17: The distinctive erythematous bandlike lesion on the mucosa of the upper lip has appeared this morning. Has a suggestive scrotal lesion, which made its appearance two days ago.

July 19: Mouth lesions have faded. Scrotal lesion is less marked.

July 21: Scrotum practically normal.

August 16: Suggestive buccal lesions again appeared on August 10 but have completely faded. Four days ago weighed 9.5 kilograms.

March 15, 1927: Has presented no evidence of blacktongue since early last August—that is, during a period of about seven months. Weighs 10.2 kilograms. Experiment is discontinued.

Results and conclusions.—In none of the five test animals during the first or exclusively curative phase of the study could a beneficial effect be recognized.

In the initial stage of the preventive test the ingestion daily of a quantity of boiled carrots representing 300 grams, or about 25 to 40 grams per kilogram of body weight, of the raw dressed vegetable failed to prevent completely the development of evidence of blacktongue in any one of the test animals. The increase in the allowance of boiled carrots to the equivalent of 600 grams, or to about 50 to 85 grams of the raw vegetable per kilogram of body weight, was followed by a slow clearing up of the evidence of blacktongue, with subsequent freedom from all indications of the disease during periods of observation of between 5½ and 10 months. Thus over 40 grams of the vegetable per kilogram of body weight were required as a supplement to our basic diet No. 123 before a blacktongue preventive action became definitely appreciable. This would seem to indicate that carrots contain the blacktongue preventive, but in relatively small amount. The failure in pellagra prevention reported by Goldberger and Wheeler (13), cited in the foregoing, would thus appear to be entirely consistent with this result in the canine disease.

RUTABAGAS

Shortly after beginning the study of carrots, presented in the foregoing, we undertook a study of the blacktongue preventive action of the rutabaga turnip. At about the same time a pellagra-preventive study of this vegetable was begun by Goldberger and Wheeler (13) at the Georgia State Sanitarium. It was at first planned to work with the common white turnip in both investigations, but finding that an adequate supply of this vegetable throughout the year would be less certain than that of the rutabaga, the latter was finally selected for study in both. The results of the study of pellagra prevention, already reported by Goldberger and Wheeler (13), indicate that the cooked dressed rutabaga contains so little of the pellagra preventive that the daily ingestion of the equivalent of 1 pound of the raw dressed vegetable was without recognizable pellagra preventive action. The determination of what the ingestion of a larger quantity might have shown with respect to preventive potency was not attempted.

Our study of the rutabaga in blacktongue is presented in the following:

EXPERIMENT 22

This was a test of the blacktongue preventive action of the rutabaga turnip when fed as a supplement to our basic blacktongue-producing diet No. 123. (Table 1.)

The rutabagas were peeled as for human consumption, run through a meat chopper, and then cooked in a small amount of added water in a double boiler for about two hours. Thus cooked and tender they were offered daily in weighed amounts to each dog apart from

the basic diet. As it soon appeared that the dogs would take the cooked rutabagas better if mixed with some of the other food, this practice was adopted and maintained to the end of the experiment. As in the case of the carrots, the ration of rutabagas was served the dogs shortly before noon of each day. What was found unconsumed a few hours later was forcibly fed. Incidentally, as with the carrots, a small, negligible part of the rutabaga ration was unavoidably wasted.

The preventive dose begun with was the same as that with carrots, namely, the cooked equivalent of 300 grams of the raw dressed vegetable per dog per day. As the test animals differed somewhat in weight, this made a dose that varied for the respective animals between 25 and 35 grams per kilogram of body weight. At the end of about six weeks of this dosage one of the animals manifesting suggestive evidence of blacktongue, and thus of a probable preventive inadequacy, the daily allowance was at once doubled for all of this lot of dogs in order, if possible, to insure a preventive effect. The allowance thus increased was maintained to the close of the experiment, which lasted in all about 13½ months.

Four test animals, dogs 67, 73, 93, and 95 were used. The significant details relating to each of the animals are as follows:

Dog 67.—Male. Whelped in the laboratory November 25, 1923. Reared and maintained on stock diets up to February 2, 1926.

February 2, 1926: In good condition. Weighs 9.6 kilograms. Begins basic diet No. 123 and a daily supplement of boiled rutabagas representing 300 grams, or about 30 grams per kilogram of body weight, of the raw dressed vegetable.

March 16: Presented, two days ago, a slight injection of the floor of the mouth, which was distinctly perceptible yesterday but is entirely gone this morning. This evanescent but suggestive indication of blacktongue and, thus, of a preventive inadequacy of the allowance of the rutabagas, makes an increase desirable in order if possible to insure a preventive effect. Accordingly, the daily supplement of boiled rutabagas is this day increased to the equivalent of 600 grams, or about 60 grams per kilogram of body weight, of the raw dressed vegetable.

January 13, 1927: Presents this morning an ill-defined, faintly reddened patch on the mucosa of the upper lip in the region of the canine teeth of each side. Mucosa of the cheeks is slightly flushed and that of the floor of the mouth is slightly injected. Weighs 7.8 kilograms.

January 14: Mouth is normal this morning.

March 15, 1927: Except for the evanescent but suggestive indication of blacktongue in evidence January 13, 1927, this animal has been free of recognizable indications of blacktongue during a period of one year. Experiment is discontinued.

Dog 73.—Bitch. Acquired March 19, 1924. Up to December 19, 1925, suffered two uncertain, evanescent, and one definite attack of blacktongue, the latest of which began December 17, 1925. On stock diet for reconditioning from December 19, 1925, to February 2, 1926.

February 2, 1926: In good condition. Weighs 9.4 kilograms. Begins basic diet No. 123 and a daily supplement of boiled rutabagas representing 300 grams, or about 30 grams per kilogram of body weight, of the raw dressed vegetable.

March 16, 1926: Has presented no suggestion of blacktongue, but by reason of suggestive indications presented by dog 67, the daily supplement of boiled rutabagas is this day doubled. Weighs 9.9 kilograms.

March 15, 1927: Has presented nothing suggestive of blacktongue during the period of 13½ months since the beginning of the experiment. Weighs 9.5 kilograms. In good condition. Experiment discontinued.

Dog 93.—Male. Acquired November 5, 1925. On stock diet to February 2, 1926.

February 2, 1926: In good condition. Weighs 12.2 kilograms. Begins basic diet No. 123 with a daily supplement of boiled rutabagas representing 300 grams, or about 25 grams per kilogram of body weight, of the raw dressed vegetable.

March 16, 1926: Has presented nothing suggestive of blacktongue, but, as in the case of dog 73, the daily supplement of boiled rutabagas is doubled. Weighs 12.9 kilograms.

March 15, 1927: Has presented nothing suggesting blacktongue during the period of 13½ months since the beginning of the experiment. In good condition. Weighs 13.7 kilograms. Experiment is discontinued.

Dog 95.—Male. Acquired November 30, 1925. On stock diet to February 2, 1926.

February 2, 1926: In good condition. Weighs 8 6 kilograms. Begins basic diet No. 123 with a daily supplement of boiled rutabagas representing 300 grams, or 35 grams per kilogram of body weight, of the raw dressed vegetable.

March 16, 1926: As in the case of dogs 73 and 93, the daily supplement of boiled rutabagas is this day doubled. Weighs 8.6 kilograms.

March 15, 1927: Has presented no indications of blacktongue during the experimental period of 13½ months. Food consumption has been variable; has lost some in weight, which is 7.3 kilograms. Experiment is discontinued.

Results and conclusions.—Of the four test animals, one (dog 67) presented transient but suggestive indications of blacktongue about 40 days after beginning the experiment and while receiving daily the boiled equivalent of about 30 grams of the raw dressed vegetable per kilogram of body weight. The same animal again presented evanescent signs suggesting blacktongue about 10 months after beginning a daily allowance of the boiled equivalent of about 60 grams of the raw dressed vegetable per kilogram of body weight. None of the other three animals (dogs 73, 93, and 95) presented any evidence of blacktongue at any time during the test period of 13½ months. It would appear therefore that the rutabagas contain the blacktongue preventive, but in relatively small amount, since the cooked equivalent of upward of 60 grams of the raw dressed vegetable per kilogram of body weight may be needed for complete protection of the dog.

It may be noted that the failure reported by Goldberger and Wheeler (12) to recognize any pellagra preventive effect following the daily ingestion of the cooked equivalent of one pound of raw dressed rutabagas is entirely consistent with this result in blacktongue.

RELATION OF BLACKTONGUE TO PELLAGRA

In the foregoing we have presented the results of our study of the blacktongue-preventive action of a series of foodstuffs of considerable variety, numbering 16 in all. Since the principal object of that study has been to secure evidence concerning the relation of the blacktongue preventive to the pellagra preventive and, thus, of blacktongue to pellagra, an attempt has been made to correlate the blacktongue-preventive potency of each foodstuff to its pellagra-preventive potency where this was known.

As will have been seen, 11 of the foodstuffs (namely, maize, wheat germ, cowpea, soy bean, milk, butter, cod-liver oil, lean beef, tomato, carrot, and rutabaga) have been studied for their preventive action in both conditions. In the case of eight of these (maize, wheat germ, cowpea, milk, butter, cod-liver oil, lean beef, tomato) our knowledge of their preventive potency or lack of it for the two conditions under consideration is of such character as to permit of a rough but sufficiently satisfactory comparison for the present purpose; in each one of these eight the preventive potency for pellagra is, as has been pointed out, strikingly similar to that for blacktongue.

With respect to 3 of the 11 foodstuffs, namely, the soy bean, carrot, and rutabaga, our knowledge of their pellagra-preventive potency is not sufficient to permit of satisfactory comparison with their blacktongue-preventive action. Such general indications as are afforded, however, justify the expectation that additional investigation of their preventive potency for pellagra will reveal this to be similar to their preventive potency for blacktongue.

In brief, then, it seems clearly indicated that, so far as they have been studied, the foodstuffs that appear to be good sources of the blacktongue preventive also appear to be good sources of the pellagra preventive; those that appear to be poor sources of, or lacking in, the blacktongue preventive likewise appear as poor sources of, or lacking in, the pellagra preventive. This, it should be noted, is not a mere similarity in distribution of the respective preventive essentials among the foodstuffs—it is a similarity in the potency of the action of those foodstuffs in the respective pathological conditions and, thus, this would seem to constitute evidence of weight pointing to the identity of the preventive essentials and, therefore, to the identity of blacktongue and pellagra.

Considering the foregoing evidence in conjunction with the evidence presented in our previous communications (2), (3), namely, the striking clinical resemblance of the disease in the dog to the disease in man, the suggestion of a common etiology indicated by the successful production of the disease in the dog by feeding pellagra-producing diets, the effectiveness of dried yeast and a dried aqueous extract of yeast as preventives of both conditions, together with the

fact of the successful production of a pellagra-like condition in the albino rat by feeding a diet deficient in a food essential which is indistinguishable from the preventive of blacktongue [1] (14), as well as with the evidence revealed by Denton's study (5) showing that there is a marked similarity in the gross and microscopic tissue changes of blacktongue and pellagra—considering all this evidence as a whole, it would seem highly probable, if not certain, that experimental blacktongue and pellagra are essentially identical conditions and, thus, that the preventive of blacktongue is identical with the pellagra preventive or factor P-P.

If this conclusion is, as we believe, sound, it manifestly follows that the results of tests of preventive action carried out in the dog are applicable to the disease in man and, thus, that the indications presented in the foregoing with respect to the blacktongue-preventive potency of certain of the foodstuffs (liver, salmon, egg yolk) not yet studied directly in pellagra may be accepted as having corresponding significance for that disease. We would, accordingly, recommend liver, salmon, and egg yolk for use in the treatment and prevention of pellagra.

SUMMARY AND CONCLUSIONS

The blacktongue-preventive potency of 16 foodstuffs has been studied and correlated to the pellagra preventive potency (or lack of it) of those, eleven in number, for which this was known, with the following results:

Maize, if it contains any, is a poor source of the preventive for both blacktongue and pellagra.

Whole *wheat* contains the blacktongue preventive, but in small amount.

Commercial *wheat germ* contains, and may be rated as a relatively good source of, the preventive for both blacktongue and pellagra.

The *cowpea* contains, but is a poor source of, the preventive for both blacktongue and pellagra

The *soy bean* contains the blacktongue preventive, but in relatively small amount, appreciably more, however, than the cowpea, but considerably less than the extracted wheat germ. So far as it goes the experience with the soy bean in the human disease is, at least, not inconsistent with that in the experimental disease of the dog.

Milk contains the preventive for both the human and the canine disease, but contains it in relatively small amount.

Butter, while not devoid of it, is a relatively very poor source of the blacktongue preventive, a conclusion that is in harmony with the experience with butter in pellagra.

Cod-liver oil would seem very poor in or lacking the preventive for both blacktongue and pellagra.

---

[1] Since the experimental pellagra-like condition in the albino rat appears to be due to a deficiency of the same food essential as is experimental blacktongue, that is to say, since these two conditions appear to be etiologically indistinguishable, proof of the identity of blacktongue and pellagra is also, of course, proof of the fundamental identity of the condition in the rat and the disease (pellagra) in man.

Cottonseed oil contains little, if any, of the preventive for blacktongue. No specific study of the effectiveness of this oil in pellagra has been made; on the basis of general experience it seems unlikely that this oil contains the pellagra preventive in significant amounts.

Beef muscle is a good source of the preventive for both blacktongue and pellagra.

Pork liver is a good source of the blacktongue preventive; it has not yet been studied in pellagra.

Canned salmon contains the blacktongue preventive. A study of its effectiveness in pellagra is in progress.

Egg yolk contains the blacktongue preventive; a specific study of its value in pellagra has not yet been undertaken.

The canned *tomato* contains the preventive for both blacktongue and pellagra, but in relatively small amount.

The *carrot* contains, but is a relatively poor source of, the preventive of blacktongue. Its reported failure in pellagra prevention is consistent with the indications of its feebleness as a blacktongue preventive.

The *rutabaga* turnip contains, but is a relatively poor source of, the blacktongue preventive. Its failure in pellagra prevention is consistent with its poverty in the blacktongue preventive.

So far as they have been studied, the foodstuffs that appear to be good sources of the blacktongue preventive also appear to be good sources of the pellagra preventive; those that appear to be poor sources of, or lacking in, the blacktongue preventive likewise appear to be poor sources of, or lacking in, the pellagra preventive.

Considering the available evidence as a whole, it would seem highly probable, if not certain, that experimental blacktongue and pellagra are essentially identical conditions and thus that the preventive of blacktongue is identical with the pellagra preventive, or factor P-P.

On the basis of the indications afforded by the test in the dog, liver, salmon, and egg yolk are recommended for use in the treatment and prevention of pellagra in the human.

[1] The maize meal, wheat farina, rice, cowpeas (previously coarsely ground), and sodium chloride are stirred into water and cooked about 1½ hours. Then the other ingredients are well stirred in and the total weight is brought to 2,000 grams with water. The finished mixture is served to the dog in suitable calorie portions.
[2] Whole white maize meal, sifted as for human consumption.
[3] For origin see text.

TABLE 10.—*Composition of Beltsville butter diet No. 115B* [1]

[Total calories, 2,415]

Articles of diet	Quantity	Nutrients: Protein	Fat	Carbohydrate
	Grams	*Grams*	*Grams*	*Grams*
Corn meal [2]	200	16.8	9.4	148.0
Wheat farina (Quaker brand)	100	11.4	1.0	75.0
Rice, white	28	2.2		22.1
Cowpeas (*Vigna sinensis*)	14	3.0	2.0	8.5
Beltsville butter [3]	160	1.6	128.0	
Sodium chloride	10			
Calcium carbonate	3			
Tomato juice (canned tomatoes)	130			
Total nutrients		35.0	140.4	253.6
Nutrients per 1,000 calories		14.4	58.0	104.8

[1] The maize meal, wheat farina, rice, cowpeas (previously coarsely ground), and sodium chloride are stirred into water and cooked about 1½ hours. Then the other ingredients are well stirred in and the total weight is brought to 2,000 grams with water. The finished mixture is served to the dog in suitable calorie portions.
[2] Whole white maize meal, sifted as for human consumption.
[3] For origin see text.

TABLE 11.—*Composition of butterfat diets No. 180A*[1], *No. 180B*[1], *and No. 180C*[1]

[Total calories, 2,400]

Articles of diet	Quantity	Nutrients		
		Protein	Fat	Carbohydrate
	Grams	*Grams*	*Grams*	*Grams*
Corn meal [2]	300	25.4	14.1	222.0
Wheat germ (ether-extracted)	25	7.3		15.7
Casein (purefied) [3]	32	28.0		
Milledgeville butterfat (in diet No 180A) / Vermont butterfat (in diets No. 180B and No. 180C)	115		115.0	
Cod-liver oil	5		5.0	
Salt mixture [4]	18			
Tomato juice (in diets No. 180A and No 180B only)	130			
Total nutrients		60.7	134.1	237.7
Nutrients per 1,000 calories		25.2	55.8	99.0

[1] The maize meal and wheat germ are stirred into water and cooked about 1½ hours. Then the other ingredients are well stirred in (omitting the tomato juice in the case of diet No. 180C) and the final weight is brought to 2,400 grams with water (so that 1 gram represents 1 calorie). The mixture is served to the dog in suitable calorie portions.
[2] Whole white maize meal sifted as for human consumption.
[3] Commercial casein leached for a week in daily changes of acidulated water, after McCollum (15).
[4] After Osborne and Mendel (16).

TABLE 12.—*Composition of cottonseed oil diet No. 302* [1]

[Total calories, 2,400]

Nutrients per 1,000 calories		38.1	33.5	136.0

[1] The dried egg yolk, maize meal, cowpeas (coarsely ground), and sodium chloride are stirred into water and cooked for about 1½ hours. Then the other ingredients are well stirred in and the final weight is brought to 2,400 grams with water (so that 1 gram represents 1 calorie). This food mixture is served to the dog in suitable calorie portions.
[2] For method of preparation see text.
[3] Whole white maize meal sifted as for human consumption.
[4] Commercial casein leached for a week in daily changes of acidulated water, after McCollum (15).

PUBLIC HEALTH ENGINEERING ABSTRACTS

German Developments in Refuse Disposal. John H. D. Blanke. *The American City*, vol. 38, No. 2, February, 1928, pp. 87–89. (Abstract by J. B. Harrington.)

The developments of refuse disposal in Germany since 1893 are set forth briefly in this article. The shaft furnace in which heavy layers of refuse are burned was first developed at Hamburg. Other recent and successful developments are the removal of combustion residues by machinery, and, in 1925, the installation of fire-tube boilers in combination with the furnace unit. At the Hamburg plant, consisting of 12 furnace units, four of which are equipped with fire-tube boilers, one of the units was replaced with a furnace provided with a grate-residue remover and a vertical-tube boiler. Tests on this unit indicate that it will handle 80 tons of refuse per 24 hours, as compared to 30 tons per 24 hours for the old units. Further successful developments along this line are an increased grate area, a slack-forming zone of water-cooled iron surface covered with stone, the vibrating or oscillating blower, and the air heater. Combustion usually lasts about 20 minutes. The flue gases pass through the ashing chamber, where they are burned further, and then successively through a fire-tube boiler, a flue chamber with steam superheater, two horizontal flue-tube boilers, a second flue chamber, electric filter, and chimney. The by-products of the plants are 45 to 50 per cent slack; 1 per cent old iron, 0.7 per cent magnetic slack, 5 to 20 per cent flying ash, 0.55 to 3.3 pounds steam per pound of refuse, 353 to 530 cubic feet of hot water at 122° F. in one hour from one furnace unit.

House Refuse Collection, E. H. Radcliffe. *The Surveyor*, vol. 73, No. 1888, March 30, 1928, pp. 375–376. (Abstract by H. N. Old.)

In this paper, presented at a recent meeting of the Royal Sanitary Institute held at Taunton, the various methods of house storage of refuse are discussed. The ash pit is a requirement in some jurisdictions, although the more common types of tubs, buckets, and boxes are in general use. The evils of curb-side collection are given and coincide with similar conditions in the United States.

The desirability of the collection from the rear of the premises is stressed, despite the factor of additional cost of this service. The author advocates a system of collection somewhat identical with the trailer method used rather generally throughout this country in the larger communities.

Another method described is that of yard collection, but allowing the loaders, usually two men, to carry the containers to the curb while the van goes to the disposal ground. In this way much time is saved and the loaders can usually judge the number of premises they may serve while waiting for the return of the van to pick up the material lined up at the curb.

At Taunton the town is divided into 15 districts, and three electric vehicles and a 30-hundredweight "Morris lorry" are used for curb-side collection. The schedule for a week is given as example of the system and indicates that the collection of refuse and scavenging is taken care of by the same outfits by systematic apportionment of the time.

Refuse Disposal as a Factor in National Economy. F. D. Ogden. *The Journal* of the Institution of Municipal and County Engineers, vol. 54, No. 15, January 24, 1928, pp. 971–979. (Abstract by Harriet S. Ryan.)

Salvage operations properly conducted attain the object of definitely disposing, in a hygienic manner, of objectionable refuse, and, in addition, open up an appreciable source of revenue. Tipping and other insanitary methods of disposing of refuse are fast passing, giving place to the refuse destructor. Refuse is not actually destroyed, but merely changed in form so as to be rendered innocuous. It is the salvage of refuse so dealt with which has prompted the

writer to make these notes. He quotes the law relating to scavenging in general as set out in the public health act of 1875. He endeavors to encourage interest in the subject by means of examples of the various residuals it is possible to obtain from the average refuse of a town of 30,000 inhabitants.

Before embarking upon a salvaging scheme, it is necessary to institute tests to ascertain the average amount of the various components, which vary considerably according to locality, season, etc. The refuse is sorted and the salable material is sent to the necessary salvage plant, while all which should be burned is committed to the furnace. Every available particle of refuse is utilized.

In following the various materials to the respective salvage plants and indicating the possibilities of salvage, the writer reviews that aspect of scavenging dealing with the ultimate disposal of refuse in such a manner as to obviate some of this waste by its utilization, in changed form, for various purposes.

Water Supply, Sewage Treatment, and Refuse Disposal in 1927. H. B. Cleveland. *Public Works*, vol. 59, No. 1, January, 1928. pp. 14–18. (Abstract by R. J. Faust.)

Refuse disposal.—The trend has been almost wholly to construct incinerators rather than build reduction plants or develop hog farms.

The Buffalo, Los Angeles, Toledo, Birmingham, Philadelphia, and New York City incinerator installations have been the more recent notable plants. At Cleveland a reduction plant is being planned, and at Indianapolis the reduction plant started operation within the year.

Treatment of Packing-Plant Wastes. Frederick G. Nelson. *The Canadian Engineer*, vol. 53, No. 25, December 20, 1927, pp. 627–629. (Abstract by R. E. Thompson.)

A description of the activated sludge plant operated by the Iowa State College Engineering Experiment Station at the packing works of J. E. Decker & Son, Mason, Iowa, with an outline of operating experiences. The plant consists of a Dorco rotary screen, primary settling tank, two aeration tanks, secondary settling tank, and a sludge reaeration tank. Both settling tanks are of the Dorr type, equipped with thickeners. The average hourly flow varied from 200–490 gallons per minute, dropping to 125 gallons per minute on Sundays. During periods of low flow, difficulties were experienced, due to the primary settling tanks becoming septic, this condition giving rise to disturbances in the purification process. With a sludge return of 50 gallons per minute, the theoretical detention period in the sludge reaeration tank is five and one-half hours. This tank, which was installed after the plant had been in operation some time, has effected a great improvement. The short period of aeration has little effect, however, when the sludge is septic. Increasing sludge return to 150 gallons per minute by returning sludge directly to the aeration tank during low flow periods has been found to facilitate the building up of a large amount of sludge for use when the flow increases.

One of the most troublesome factors encountered has been the rising of sludge in the final settling tank. This occurs when the sludge is under or over aerated or slightly septic. Applying a continuous spray of water to the scum formed has been partially successful in causing the sludge to resettle. Carefully controlling the air supply is the best method of combating this condition.

On some days extreme foaming has occurred in the aeration tanks, the foam at times covering the tanks to a depth of 6 feet and the ground to depth of 1 to 4 feet for a distance of 50 feet. Foaming apparently occurs at certain intervals when the tanks are changing from an underaerated to a fully aerated condition. Probably the most effective remedy would be either the use of oil in the tanks or the application of a flat, horizontal spray of water which would tend to cut the foam.

To correct unequal distribution of air, the tanks were dewatered and cleaned. A heavy deposit of sand and organic matter was found on the entire bottom of the aeration tanks to a depth of 4–6 inches. The filtros plates were cleaned by scrubbing, soaking in hydrochloric acid (specific gravity 1.14), and finally washing with hot water applied through a nozzle under pressure. The method employed for testing the loss of head through the plates before replacing them is outlined.

Experiments have been carried out on dewatering the sludge with an American continuous filter. The primary sludge, which contains 6 per cent dry solids, when treated with 10 pounds of alum per 1,000 gallons, filters readily to 71 per cent moisture. A few determinations have indicated an erratic solid content in the activated sludge varying from 0.25 to 1.5 per cent. A mixture of 75 per cents activated and 25 per cent primary sludge treated with 5 pounds of alum per 1,000 gallons gave a cake with 75 per cent moisture or a little higher. A few tests with ferric chloride also gave good results, but the moisture content of the cake was somewhat higher. The mixture of sludges filters more rapidly than the ordinary sludge alone. It is not expected that the plant will be able to treat successfully the wastes during the approaching peak of the killing season.

Water Pollution Control: Cannery Wastes. Homer S. Murphy, J. M. Hepler, and E. F. Eldridge. A Compilation Covering Activities, Experimental Work and Cooperative Investigations as Conducted by the Department of Conservation, Department of Health and the Michigan Canners Association. 18 pages. (Abstract by D. S. Abell.)

The first section of this pamphlet mentions the history of experimental work on canning-factory waste. Previous work done in Michigan was summarized in the statement, "The biological process might be slower than the chemical treatment process, but past experiments indicate that it could be operated efficiently and at less expense." Since 1925 Michigan has had a law which makes it "the duty of the Department of Conservation; * * * to guard against the pollution of lakes and streams within the State and to enforce all laws provided for that purpose with all authority granted by law and to foster and encourage the protecting and propagation of game and fish." Previous investigations at the following places are each reviewed: New Jersey, 1910; Washington, Ill., 1913; Fremont, Mich., Amelia, Ohio, 1916; Columbus, Ohio, Brockport, N. Y., and Poynette, Wis., 1916. Next follows a condensed report of the operation of the Michigan Canners Association experimental waste treatment plant located at the W. R. Roach & Co.'s plant at Kent City. Members of the association voted to assess themselves a sum of 0.2 of a cent per can based on the 1925 pack for the purpose of studying the problem. The plant consisted of fine screens, "which every canning plant should have," settling tanks, one of which could be used for digestion; and filter beds of different types. Sprinkling filters gave quite satisfactory results. The intermittent sand filters, however, showed a tendency to form a hard crust. Cinder filters will be abandoned. The small amount of sludge obtained indicates the possibility of supplanting the tanks with fine screens. A grit chamber may help. A portable plant is planned. It is hoped that after the next (1927) season definite recommendations can be made to the industry with reference to treatment of all canning wastes.

Sprinkling Filter Planned for Expansion. Henry R. Buck. *The American City*, vol. 38, No. 2, February, 1928, pp. 107–108. (Abstract by J. B. Harrington.)

Watertown, Conn., has an area of 18,750 acres; population of the town is 6,000, and of the district 2,000. The wastes to be treated are almost entirely of domestic nature. The plant is designed to handle 200,000 gallons per day, with an ultimate flow of 500,000 gallons. The tank with two units each 20 by 39

feet, 8 inches square, has been constructed. Each unit has an 8-inch sludge line. The total sludge capacity is 11,880 cubic feet, or 5.9 cubic feet per capita. Gas vents are a minimum width of 1 foot 6 inches, giving 30 per cent of the total area. Each tank has two flow chambers, with a minimum capacity of 9,750 gallons. The retention period when all chambers are in use is 2¼ hours. Two grit chambers each 5 feet 2 inches by 2 feet 6 inches by 7 feet deep with removable racks, have been constructed at the end of the 20-inch line. The sludge bed was built in two sections, each with 2,175 square feet area. Two siphon chambers operating on 8.7-foot head have been provided. The sprinkling filters, only one of which has been constructed, are 110 feet by 75 feet 3 inches, with ⅞-inch nozzles on 13-foot centers. During the winter months construction was carried on by the use of calcium chloride. The cost of the treatment plant was $80,000, and the cost of 17,964 feet of sewer was $75,000.

The Administration of the Milk and Dairies Order, 1926. W. O. Coates. *Journal Royal Sanitary Institute*, vol. 48, No. 8, February, 1928, pp. 462–469. (Abstract by H. A. Whittaker.)

This article gives a general discussion of the administration of the Milk and Dairies Order of England (passed in 1926) which regulates dairy premises and their supervision by the sanitary authority.

For purposes of administration, the author makes several divisions of the order as follows: (1) The two administrative authorities; (2) the administrative officers; i, e., the veterinary inspector, the medical officer of health, and the sanitary inspector. Divisions may be formed for grouping the duties of these authorities and officers; (3) the sanitary inspector being responsible for the administration of the greater portion of the order, this portion is divided to emphasize his varied duties, thus: (*a*) Office administration, (*b*) general routine dairy requirements, (*c*) special requirements applicable to cow keepers, (*d*) constructional requirements, (*e*) distributional routine requirements.

Only the topics contained under No. 3 are taken up in this paper. The author outlines the various requirements and gives a brief interpretation and discussion of each. Brief discussions of certain parts of the order by persons interested in its administration are appended to the article.

Connecticut Standard Test for Dirt in Milk. Friend Lee Mickle. Connecticut *Health Bulletin*, vol. 42, No. 2, February, 1928, pp. 27–30. (Abstract by W. H. Haskell.)

The author points out that the standard disks prepared according to the Standard Methods of Milk Analysis of the American Public Health Association were found to be inadequate as a guide for Connecticut. Laboratory results from various State laboratories were not uniform with results of tests. Standard Methods is also criticized for not specifying certain specific apparatus to be used in making the test. It is also stated that the sizes of the particles of dirt on the different standards varied greatly, and that the kind of dirt used in different laboratories varied in color to a greater extent than had previously been thought possible. An additional photograph of disks has been adopted (in addition to photographs shown on page 33 of fifth edition of Standard Methods) showing 0.25, 0.50, 0.75, and 1 milligram of dirt per pint and the Wisconsin or Lorenz model of sediment tester chosen as the standard. The exact method of carrying out the adopted test is included in the article.

The Purification of Contaminated Oysters in Natural Waters. Charles Krumwiede, William H. Park, Georgia Cooper, Marie Grund, Charles Tyler, and Carolyn Rosenstein. *American Journal of Public Health*, vol. 18, No. 1, January, 1928, pp. 48–52. (Abstract by F. O. Almquist.)

An interesting article on the investigation of the cleansing effect of changing sea water on contaminated oysters. Two lots of freshly dredged oysters were

obtained, one lot from waters where the experiment was to be carried out and the other from distant waters. Each lot was equally divided, one batch of each lot being lightly contaminated and the other heavily contaminated. They were then placed in the natural water for the test. The area in which the tests were made was located near condemned oyster beds. The viability of *B. typhosus* in sea water was also determined.

From the tables compiled it was shown that *B. typhosus* survives roughly 2 to 3 weeks in oysters and 3 weeks in sea water.

It is believed that contaminated oysters transferred to new water would require for purification about the same time equal to the length of time of survival of *B. typhosus* in sea water. It is then concluded that an ordinance allowing the transfer of oysters from questionable to clean waters providing no dredging be allowed for four weeks after the transfer would give a good margin of safety.

An Investigation into the Effect of Pasteurization on the Bovine Tubercle Bacillus in Naturally Infected Tuberculous Milks. L. J. Meanwell. *The Journal of Hygiene*, vol. 26, No. 4, October, 1927, pp. 392–402. (Abstract by W. D. Tiedeman.)

Results obtained by other workers in studying the effect of Pasteurization upon the tubercle bacillus in milk, either naturally or artificially infected, are reviewed. The author points out that apparent differences may be due in part to a greater virulence of the organisms in naturally infected milk. He also considers the possibility of latent infections, and in his experimental work kept guinea pigs 100 days or more.

He Pasteurized separately, in special laboratory apparatus designed to heat every particle of the milk to a uniform and accurately determined temperature, the naturally infected milk from 3 cows known to be suffering from tuberculosis of the udder. The milk from cow No. 1 was abnormal in appearance, a flocculent mass separating out on standing. The milk from the other two cows was normal, although slightly darker in color at times.

The centrifugalized deposit and cream from Pasteurized, naturally infected milk was injected into guinea pigs with the following results: Two pigs out of 284 injected developed tuberculosis with milk treated at 145° F. for 30 minutes, 140° F. for 30 minutes, and 140° F. for 20 minutes, respectively, whereas 10 pigs out of 12 injected developed tuberculosis with milk treated at 138.8° F. for 20 minutes. Coagulated material collecting on the cooler in some of the experiments was ground up with saline and injected into guinea pigs with the following results: Two pigs out of 44 injected developed tuberculosis with material from milk treated at 145 ° F. for 30 minutes and at 140° F. for 20 minutes. None of the 6 pigs injected with this material from milk treated at 138.8° F. for 20 minutes developed tuberculosis.

The author mentions collecting control samples, but gives no results, leaving an open question as to the significance of the large number of negative results obtained with Pasteurized milk.

DEATHS DURING WEEK ENDED MAY 26, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended May 26, 1928, and corresponding week of 1927. (From the Weekly Health Index, May 31, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended May 26, 1928	Corresponding week, 1927
Policies in force	71, 266, 788	67, 772, 503
Number of death claims	15, 183	11, 919
Death claims per 1,000 policies in force, annual rate	11. 1	9. 2

Deaths from all causes in certain large cities of the United States during the week ended May 26, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, May 31, 1928, issued by the Bureau of the Census, Department of Commerce)

PREVALENCE OF DISEASE

No health department, State, or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

ADMISSIONS TO HOSPITALS FOR THE INSANE, FEBRUARY, 1928

Reports for the month of February, 1928, showing new admissions to hospitals for the care and treatment of the insane have been received by the Public Health Service from 85 institutions located in 30 States, the District of Columbia, and the Territory of Hawaii.

104380°—28——6

Sixteen of these institutions were corporate or private. These hospitals reported a total of 118,122 patients on February 29, 1928, including those on parole.

The following table shows the numbers of new admissions for the month of February, 1928, by psychoses.

First admissions to 85 hospitals for the insane, February, 1928

Psychoses	Male	Female	Total
Traumatic psychoses	11	0	11
Senile psychoses	112	91	203
Psychoses with cerebral arteriosclerosis	68	35	103
General paralysis	140	28	168
Psychoses with cerebral syphilis	20	10	30
Psychoses with Huntington's chorea	0	4	4
Psychoses with other brain tumor	2	0	2
Psychoses with other brain or nervous disease	20	8	28
Alcoholic psychoses	68	3	71
Psychoses due to drugs and other exogenous toxins	6	3	9
Psychoses with pellagra	6	16	22
Psychoses with other somatic diseases	20	36	56
Manic-depressive psychoses	150	154	304
Involution melancholia	7	24	31
Dementia præcox (schizophrenia)	249	162	411
Paranoia and paranoid conditions	25	17	42
Epileptic psychoses	36	31	67
Psychoneuroses and neuroses	11	22	33
Psychoses with psychopathic personality	23	12	35
Psychoses with mental deficiency	43	29	72
Undiagnosed psychoses	61	55	116
Without psychosis	57	25	82
Total	1,135	765	1,900

Fifty-nine and seven-tenths per cent of the new admissions were males and 40.3 per cent were females, giving a ratio of 148 males per 100 females. The 85 institutions on February 29, 1928, had 62,496 male and 55,626 female patients, the ratio being 112 males per 100 females.

Undiagnosed psychoses constituted 6.1 per cent of the total admissions; dementia præcox, 21.6 per cent; manic-depressive psychoses, 16 per cent; senile psychoses, 10.7 per cent; general paralysis, 8.8 per cent; psychoses with cerebral arteriosclerosis, 5.4 per cent; and 4.3 per cent were recorded as without psychosis.

TYPHOID FEVER IN RUTLAND, VT.

The Secretary of the Department of Public Health of Vermont reports an epidemic of typhoid fever in the city of Rutland, Vt., from March 25 to April 14, 1928, which was traced to a healthy carrier employed in a dairy. There were 15 primary cases, 1 secondary case, and 3 deaths. The carrier was 63 years of age and gave a history of typhoid fever when about 15 years old. Eighteen years ago he developed cholecystitis and was operated upon with the removal of a number of gallstones. Since that time he has been apparently well.

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 101 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,650,000. The estimated population of the 95 cities reporting deaths is more than 30,960,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended May 19, 1928, and May 21, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
42 States	1,251	1,573

City reports for week ended May 19, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during non-epidemic years

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[1] Typhus fever: 1 case at Savannah, Ga.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended May 19, 1928, compared with those for a like period ended May 21, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1928 and 1927, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,657,000 in 1928 and 31,050,000 in 1927. The 95 cities reporting deaths had nearly 30,961,000 estimated population in 1928 and nearly 30,370,000 in 1927. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, April 15 to May 19, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

THE FAR EAST

Report for the week ended May 12, 1928.—The following report for the week ended May 12, 1928, was transmitted by the Eastern Bureau of the Health Section of the Secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

Aden Protectorate.—Aden.
India.—Bassein, Bombay, Rangoon.

India.—Bassein, Calcutta, Moulmein, Vizagapatam.
Siam.—Bangkok.
French Indo-China.—Haiphong, Saigon.

Egypt.—Alexandria.
India.—Bombay, Calcutta, Madras, Moulmein, Negapatam, Rangoon, Tuticorin, Vizagapatam.
French India.—Pondicherry.
China.—Canton, Shanghai, Hong Kong.
Japan.—Osaka.
Kwantung. Dairen.
South Manchuria.—Changchun, Yingkow.

Returns for the week ended May 12 were not received from Colombo, Ceylon; Samarinda, Dutch East India; nor Vladivostok, Union of Soviet Socialist Republics.

CANADA

Provinces—Communicable diseases—Week ended May 12, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from seven Provinces of Canada for the week ended May 12, 1928, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal meningitis				2				2
Influenza	23			11	4			38
Lethargic encephalitis				3				3
Poliomyelitis				1				1
Smallpox				15		12	13	40
Typhoid fever	1	1	19	9	1			31

Quebec Province—Communicable diseases—Week ended May 19, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended May 19, 1928, as follows:

Disease	Cases	Disease	Cases
Chicken pox	15	Scarlet fever	70
Diphtheria	30	Smallpox	25
German measles	4	Tuberculosis	43
Influenza	3	Typhoid fever	16
Measles	132	Whooping cough	11

HAITI

Epidemic meningitis—Improved conditions.—Under date of May 26, 1928, the Island of Haiti was reported free from cerebrospinal meningitis, but on May 31 two cases were reported in the interior of the Island.

PERU

Lima—Mortality from all causes and from certain diseases—March, 1928.—During the month of March, 1928, 567 deaths from all causes were reported at the city of Lima, Peru, including deaths from certain diseases as follows:

Disease	Deaths	Disease	Deaths
Cerebrospinal meningitis	14	Measles	6
Gastroenteritis	49	Pneumonia	10
Influenza	19	Tuberculosis	111
Malaria	26	Typhoid fever	8

Population 200,000.

SPAIN

Mortality from all causes and from certain diseases—April–June, 1927.—During the months of April, May, and June, 1927, total mortality from all causes was reported in Spain as follows: April, 1927, 32,241 deaths; May, 1927, 31,541 deaths; June, 1927, 34,419 deaths. Deaths from certain causes were reported as follows:

DEATHS, APRIL TO JUNE, 1927

Disease	April	May	June
Bronchitis:			
Acute	1,930	1,351	1,015
Chronic	905	651	518
Cancer	1,082	1,191	1,279
Diarrhea and enteritis (under 2 years)	1,816	3,586	7,348
Diphtheria	91	74	64
Heart disease	3,246	2,817	2,465
Influenza	530	288	157
Malaria	254	330	433
Nephritis	1,045	865	841
Pneumonia	832	709	515
Puerperal fever	115	94	97
Scarlet fever	29	55	37
Smallpox	2	1	4
Tuberculosis, pulmonary	2,472	2,352	2,135
Meningeal	244	284	261
Other forms	301	344	334
Typhoid fever	244	276	321
Typhus fever	1		
Whooping cough	68	82	88
All causes	32,241	31,541	34,419

Population: 22,390,162.

UNION OF SOUTH AFRICA

Cape Province—Natal—Typhus fever—April 8–14, 1928.—During the week ended April 14, 1928, fresh outbreaks of typhus fever were reported in three districts of the Cape Province and in one district in the Province of Natal. One sporadic case was reported in a European at Durban, Natal, stated to have been imported.

Month of March, 1928.—During the month of March, 1928, 115 cases of typhus fever with 33 deaths were reported in the native population of the Union of South Africa, distributed according to Provinces as follows: Cape Province, cases, 107, deaths, 33; Natal, cases, 2; Orange Free State, cases, 4; Transvaal, cases, 2. In the European population in Natal 9 cases were reported.

VIRGIN ISLANDS

Communicable diseases—April, 1928.—During the month of April, 1928, communicable diseases were reported in the Virgin Islands of the United States as follows:

Disease and island	Cases	Remarks
St. Thomas and St. John:		
Gonorrhea	3	
Pellagra	1	
Syphilis	6	Secondary, 5.
Tetanus	1	
Whooping cough	9	
St. Croix		
Gonococcus	1	
Syphilis	5	Secondary.
Uncinariasis	1	Necator americanus.

YUGOSLAVIA

Communicable diseases—April, 1928.—During the month of April, 1928, communicable diseases were reported in Yugoslavia as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Anthrax	7	2	Measles	2,070	42
Cerebrospinal meningitis	15	7	Poliomyelitis	2	
Diphtheria	151	32	Scarlet fever	1,134	187
Dysentery	47	1	Tetanus	19	13
Leprosy	2	2	Typhus	10	2
Lethargic encephalitis	1	1	Typhoid fever	129	12

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen R C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM
THE SUPERINTENDENT OF DOCUMENTS

PUBLIC HEALTH REPORTS

VOL. 43 JUNE 15, 1928 NO. 24

THE HEALTH OF WORKERS IN DUSTY TRADES

The health hazards of dusty trades have for a long time engaged the attention of industrial hygienists. The great interest attached to this subject is due to two important facts: (1) The workmen employed in what are termed the "dusty trades" comprise the largest group of workers exposed to any one industrial hazard, and (2) exposure to certain kinds of dust has strikingly increased the mortality rate from respiratory diseases, especially tuberculosis.

While a great amount of work has been done in the study of the dust hazard in industry, there are certain questions that remain unanswered; and in the hope of contributing to a better understanding of the problem as a whole, the United States Public Health Service has undertaken special studies which are planned to cover the entire field of dusty trades. For this study the following six industries were chosen, in each of which the principal dust to which the employees were exposed represents a large group of dusts:

1. The cement industry, representing calcium dust.
2. Silver polish, representing metal dust.
3. The granite industry, representing silica dust.
4. The hard-coal industry, representing carbon dust.
5. The cotton industry, representing vegetable dust.
6. Street sweeping, representing municipal dust.

The first of these studies, dealing with the health of workers in a large Portland cement plant, has been completed and the report has recently been published as Public Health Bulletin No. 176. The investigation was conducted in one of the older, dustier plants, so that the effect of large quantities of the dust could be observed. Records of all absences from work were kept for three years, and the nature of disabling sickness was ascertained. Physical examinations were made, X-ray films were taken, and the character and amounts of dust in the atmosphere of the plant were determined.

The results of this investigation indicated that the calcium dusts generated in the process of manufacturing Portland cement do not predispose workers to tuberculosis nor to pneumonia. The workers exposed to dust experienced, however, an abnormal number of attacks of diseases of the upper respiratory tract, especially colds, acute

bronchitis, diseases of the pharynx and tonsils, and also influenza, or grippe. Attacks of these diseases serious enough to cause absence for two consecutive working days or longer occurred among the men in the dustier departments at a rate which was about 60 per cent above that for the men in the comparatively nondusty departments. Limestone dust appeared to be slightly more deleterious in this respect than cement dust.

Outdoor work in all kinds of weather, such as was experienced by the quarry workers, appeared to predispose to diseases of the upper respiratory tract even more than did exposure to the calcium dusts. In the outdoor departments of the plant, also, the highest attack rates of rheumatism were found. The study also indicated that work in a cement-dusty atmosphere may predispose to certain skin diseases such as boils, to conjunctivitis, and to deafness when cement dust in combination with ear wax forms plugs in the external ear. When the dust in the atmosphere is less than about 10,000,000 particles per cubic foot of air it is doubtful that the above-mentioned diseases and conditions would be found at greater than average frequency.

Modernization of plants and installation of ventilating systems are helping to solve the dust problem of the industry.

A limited number of free copies of the bulletin containing this report are available and may be had upon application to the Surgeon General, United States Public Health Service, Washington, D. C.

SEWAGE-POLLUTED SURFACE WATERS AS A SOURCE OF WATER SUPPLY [1]

By H. W STREETER, *Sanitary Engineer, United States Public Health Service*

One of the outstanding features of American waterworks practice is the extensive use made of surface bodies of water, and especially of streams, as a source of public water supplies. Although the actual number of public water supplies originating in underground sources is greater in this country than the number taken from surface sources, it is probable that surface sources provide at least two-thirds of the total volume of, and serve two-thirds of the population using, public water supplies.

This situation has been a natural outgrowth of the physical conditions prevailing in those sections of the United States, notably in the extensive inland areas of the Middle West and in certain portions of the Atlantic Seaboard States, in which the most intensive development of industrial cities has occurred. In these regions water readily available from underground sources is frequently insufficient in volume

[1] Read at the meeting of the American Society of Civil Engineers held at Asheville, N. C, Apr. 20, 1927, and published here by permission of the society.

and often excessively hard; hence recourse necessarily has been had to surface streams and lakes. Present indications, moreover, point to the likelihood that an increasing amount of dependence must be placed, in future years, on surface sources of water supply for public use, both in the regions named and in other sections of the country, owing to the steady diminution in the volume of underground water resulting from overdrafts made to supply increasing populations.

Coincidently with these developments has occurred a steady increase in the pollution of surface watercourses by sewage and industrial wastes, particularly in the areas above noted. This tendency has been due both to a disproportionate growth in urban population, as compared with that of rural population, and to the extension of water-carriage sewerage systems in the existing urban population groups. A good example of the rapidity with which the urban population of the Middle West has increased is furnished by population estimates for the Ohio River basin,[2] which have shown that, in the period of 25 years extending from 1890 to 1915, the urban population inhabiting this area increased 109 per cent, whereas the rural population increased but 16 per cent. It has been estimated that from 85 to 90 per cent of all domestic sewage in the Ohio River basin is discharged without any treatment into the nearest surface watercourse. The proportion of industrial wastes similarly discharged without treatment probably approaches very closely 100 per cent.

Until very recently the use of surface streams for the dual purpose of water supply and sewage disposal has been attended by comparatively few serious difficulties in obtaining reasonably safe water supplies from such sources. One contributory factor has been the ample length and relatively large volume of our major inland streams, affording an opportunity for dilution and self-purification to act as natural protective agencies. A second and more important element has been the remarkable advance made in the development and application of water purification in this country during the past three decades. In 1924 statistics collected by Gillespie[3] showed that over 23,000,000 people in the United States were being served by public water supplies purified by filtration processes.

During the past two decades or so, a steady reduction has taken place in the incidence of typhoid fever and other water-borne diseases throughout the country, notably in urban communities using purified surface water supplies. In spite of this tendency, pollution of the sources of many surface supplies has increased with such rapidity that questions have arisen as to the possibility of a failure of existing safeguards, both natural and artificial, to afford an adequate degree

[2] Public Health Bulletin No. 143, U S Public Health Service, Section III, Table No 34.

[3] Gillespie, C. G: Filtration Plant Census, 1924 Jour. Am. W W. Assoc, vol. 14, July, 1925, pp. 128-132.

of protection to such supplies. In other instances, where an ample margin of safety still exists, sanitary authorities are considering what measures may be necessary in order to forestall a situation such as has developed in the more populous areas of the country. The extent to which the availability of these sources may be affected by their progressively increased pollution is, therefore, a question of practical importance to all sanitary engineers and others who are concerned with maintaining the safety of public water supplies. It is proposed here to consider this question mainly in relation to the pollution of surface water supplies by domestic sewage, which, to a large extent, involves problems quite distinct from those resulting from their pollution by industrial wastes. It is intended, however, to mention very briefly at a later point one or two aspects of the latter which bear a particularly significant relation to the quality of water supplies in certain important industrial areas of the country.

In a broad sense, the suitability of sewage-polluted bodies of surface water as sources of water supply is dependent on a number of factors, including the following:

(*a*) The character and extent of their pollution;

(*b*) The location of the sources of pollution with respect to sources of water supply;

(*c*) The degree of protection to these sources afforded by various natural agencies, such as dilution and self-purification;

(*d*) The extent of further protection afforded by artificial water-purification; and

(*e*) The practicability and relative economy of supplementary artificial measures for reinforcing, where necessary, the protection afforded by water purification.

From a practical standpoint the most important of the five factors above named is the extent of protection afforded by artificial processes of water purification, which have become the main source of reliance in safeguarding the sanitary quality of surface water supplies in this country. Standing next in the order of relative importance is the practicability and economy of further artificial measures, both of water purification and of sewage treatment, for reinforcing the protection afforded by water purification as now currently practiced. Before discussing these two questions, however, it is proposed to consider rather briefly some of the agencies of pollution and of natural purification which influence more or less directly the relative suitability of sources of water supply located in surface bodies of water.

AGENCIES OF POLLUTION

Domestic sewage.—The most important agency of pollution affecting the quality of public water supplies derived from surface sources is, of course, domestic sewage, which contains large numbers of

intestinal bacteria originating in both human and domestic animal populations. A secondary, though sometimes highly significant agency of bacterial pollution consists of the surface drainage waters from unsewered areas, which usually contain some bacteria of intestinal origin. A third agency may be said to include, in general, certain kinds of industrial wastes, which, under some conditions, may cause unpalatable tastes in water supplies or may add measurably to the costs and difficulties involved in their efficient purification.

It has long been recognized that the numbers of intestinal bacteria contained in ordinary domestic sewage are extremely high. Thus, it commonly has been stated that the total bacterial count of sewage ranges from 1,000,000 to 10,000,000 per cubic centimeter, and that the *B. coli* content approximates 100,000 per cubic centimeter. Assuming a daily sewage flow equal to 120 gallons per capita, a fair average for the larger American cities, the *B. coli* figure given would indicate a contribution of this organism roughly approximating 200,000,000,000 per capita daily. Observations made by investigators of the United States Public Health Service in the Ohio and Illinois Rivers during the years 1914–1916 and 1921–22, respectively, indicated[4] that the average numbers of *B. coli* contributed to these streams by the metropolitan areas of Cincinnati, Louisville, Chicago, and Peoria, ranged from about 190,000,000,000 to 360,000,000,000 and averaged about 250,000,000,000 per capita daily. These figures, being derived from observations made in the stream above and below each city, represent the effect of combined sewage and surface drainage water from the areas considered. They are very considerably in excess of those which have been given as representing the normal bacterial content of human feces, which was found by MacNeal, Latzer, and Kerr[5] to be about 5,000,000,000 per capita daily, as expressed in terms of the numbers of bacteria growing on agar plates at 37° C. While making due allowance for the fact that combined sewage contains many sources of bacteria other than feces, the wide disparity of the figures above given suggests the possibility that bacteria of intestinal origin may increase in sewage for some time after its discharge into a sewerage system, or a stream, either by actual multiplication or by the progesssive disintegration of particles containing bacteria.

Industrial wastes.—In some of the industrial sections of the country, the pollution of streams and lakes by wastes from certain industries has been causing serious, and in some cases widespread, damage to

Public Health Bulletin No 143, pp 251–256 (*b*) A Symposium on Stream Pollution Part IV. Quantitative Studies of Bacterial Pollution and Natural Purification in the Ohio and Illinois Rivers. By J. K. Hoskins. Trans Am. Soc C. E , vol. 89, pp 1365–1377, also Reprint No. 1063 from Public Health Reports, January 19, 1926, pp 319–331.

[5] MacNeal, W. J., Latzer, L. L., and Kerr, J. F.. The Fecal Bacteria of Healthy Men. Jour. Infect. Dis., 1909, vol. 6, Nos. 2 and 5

sources of public water supply. In general, such damage usually is æsthetic or economic rather than hygienic in its nature, though in some instances it may and does assume the aspect last named. A good example of æsthetic damage has been afforded during the past few years by the pollution of sources of water supply located in the Ohio River basin and along the Great Lakes by phenol-bearing wastes from by-product coke plants. The unpleasant tastes in water supplies caused by the presence of minute traces of phenols and their chlorine derivatives are so well known that it is hardly necessary to dwell on them here. Examples of economic damage by industrial wastes are provided by instances in which the presence of acids and acid wastes have increased the hardness of water supplies to such an extent as to render such supplies unfit for boiler use. Although accurate and up-to-date statistics on this point are not available, it is safe to say that pollution of this general character has added many thousands of dollars annually to the cost of producing steam power in certain areas of the Middle West, notably in the upper Ohio River basin

The hygienic aspects of industrial waste pollution of water supplies, though in many cases obscured to some extent by their indirectness, are in the aggregate far from being a negligible factor in the growing complexities of water-supply sanitation. In some instances the hygienic and economic features of the problem are inseparably bound together, as, for example, where the presence of certain kinds of industrial wastes, notably from tanneries and steel mills, in raw water supplies taken for purification, increases both the difficulty and the cost of securing efficient treatment In at least one case known to the writer the physical deterioration in municipal water filtration plants resulting from the presence of excessive amounts of acid wastes in their raw water supply has diminished very measurably their average bacterial efficiency, even with highly skilled operation. In other instances, particularly those involving the causation of disagreeable tastes, water consumers have been known to have sought unsafe private sources of drinking water in preference to using the safer but less palatable public supply.

MODIFYING INFLUENCES

The extent to which the several agencies of pollution above described may influence the quality of water supplies taken from polluted streams or lakes is modified by a number of factors, of which the following are the more important: (*a*) Seasonal changes, (*b*) dilution, and (*c*) natural purification. Although the three factors enumerated are interrelated to some extent, each one of them produces more or less characteristic and measurable effects.

In considering these effects, distinction should be made between conditions prevailing in flowing streams and those frequently observed in quiescent and semiquiescent bodies of water. In the former instance the dispersion of polluting matters within the stream, though often proceeding slowly in a lateral direction, is usually extremely rapid in a vertical plane and has a tendency in general to become stabilized after a fairly definite interval of flow. In the latter case, however, the admixture of polluting wastes, discharged along the shores of lakes and ponded streams, frequently is subject to the vagaries of winds and countercurrents to such an extent that uniform dispersion in the diluting body of water seldom is attained, even after relatively long intervals of time.

Seasonal influences.—Cyclic changes of season exert their influence in two general ways: (*a*) Through their effect on variations in the bacterial content of sewage as discharged at the outfall; and (*b*) through their influence on variations in the rate of natural purification. Studies by investigators of the United States Public Health Service in the Ohio, Illinois, and Upper Mississippi Rivers have given marked evidences[6] of a fairly orderly seasonal variation in the numbers of *B. coli* per capita contributed daily to these rivers by the larger centers of sewered population, the numbers reaching a maximum during the late summer and a minimum during the winter. In the Ohio River below Cincinnati the ratio of the summer average to the winter average numbers of *B. coli* was found to be equal to 4.9, and in the Illinois River below Chicago and Peoria, 10.5 and 11.4, respectively. Similar variations were observed[7] by the International Joint Commission in the St. Clair, Detroit, Niagara, and St Lawrence Rivers below major points of pollution.

As to the causes of the phenomenon above noted, they still remain a matter for speculation. A few experiments have been made to determine whether the numbers of intestinal bacteria voided by healthy persons are consistently greater in the summer than in the winter, but the results of these experiments thus far have been inconclusive. It is possible that, under the more favorable temperature conditions prevailing in summer, organisms of the *B. coli* group actually multiply in sewage during its passage through sewerage systems and even in streams immediately below sewer outfalls, whereas under the less favorable winter temperatures they fail to do so, at least to a like extent. Regardless of its underlying causes, the phenomenon noted has been observed so consistently as to remove it from the category of mere chance. Its significance would appear to lie in the indication that the density of bacterial pollution

---

6 Public Health Bulletin No 143, pp 246-251 Public Health Bulletin No 171, pp 163-165

7 Pollution of Boundary Waters Report of Consulting Sanitary Engineer on Remedial Measures. March, 1916.

of sources of water supply located in highly polluted sections of streams, or in shoreward zones of lakes not distant from sewer outfalls, may be expected to be considerably higher during the summer months than during the winter season, all other conditions being equal. In general, this indication has been borne out by observation, subject to such modification as may be imposed by the effects of seasonal changes on the rate of natural purification, which will be discussed later under that heading.

In so far as industrial wastes are concerned, seasonal changes do not appear to exert any marked effect on their pollution density, except under conditions in which a particular industry is seasonal in its character. In some instances, notably in the pollution of water supply sources by phenol-bearing wastes, the winter season has been, in general, the far more critical; but as the gas and coke by-product industries producing such wastes are not seasonal in their activities, this condition hardly appears to be due to any seasonal variation in the amount or strength of the wastes from these industries.

Dilution.—In general, the modifying effects of dilution on the density of polluting matters discharged into natural bodies of water are fairly simple, except when complicated by secondary chemical or biological reactions following the process of dilution. If, for example, two streams (A) and (B), having, respectively, discharges equal to (Q_a) and (Q_b) and pollution densities (P_a) and (P_b) combine to form a third stream (C), the pollution density of (C) ordinarily would be:

$$\frac{P_aQ_a+P_bQ_b}{Q_a+Q_b}$$

except as modified by imperfect mixture of the two streams.

In some instances involving secondary reactions, as above noted, the changes associated with dilution are less simple Examples involving secondary chemical reactions frequently have been observed where certain types of industrial wastes, such as those of an acid character, are discharged into alkaline streams. Below the confluence of the Monongahela and Allegheny Rivers, in the Pittsburgh-Wheeling zone of the Ohio River, the admixture of the highly acid Monongahela with the less acid Allegheny produces a marked precipitation of iron salts, which are carried by the former in large quantities and are also discharged by steel mills in the Pittsburgh district. Although reactions of this kind may benefit a stream temporarily in some respects, they also may result in the formation of end-products which may interfere with the efficient operation of water purification plants.

When domestic sewage is discharged into a diluting body of water, there sometimes occurs initially a temporary increase in the bacterial content of the mixture. An increase of this kind was observed in

1914–16 in the Ohio River[8] immediately below Cincinnati, and, in 1921–22, in the Illinois River[9] immediately below the outlet of the Chicago Main Drainage Canal. In the instances cited, the bacterial content was observed to reach a fairly well-defined maximum at a point tending to move downstream during the winter but confined within a river zone extending about 25 miles below the source of pollution. It is not thus far definitely known as to whether the increase observed represents a true bacterial multiplication or whether it is the result of a progressive disintegration of "clumps" of suspended matter containing masses of bacterial cells. Possibly both processes are involved to some extent. Regardless of its underlying cause, this phenomenon suggests the possibility that sources of water supply located within river or lake zones lying in close proximity to sewer outfalls may be subject, under some conditions, to a disproportionately excessive bacterial pollution due to an increase such as above described.

Natural purification.—The fact that sewage-polluted bodies of water tend to become progressively self-purified through natural agencies is so well established that it hardly seems necessary here to dwell on it. Although the underlying causes of natural purification phenomena are little understood, the effects produced by them are well known and frequently observed. Of these effects, the most important one in relation to the use of polluted bodies of water as sources of water supply is the tendency toward a progressive decrease in the density of bacteria, especially those commonly associated with sewage, which occurs in all such bodies of water.

Quantitative studies of bacterial self-purification in flowing streams have indicated that, following the attainment of a maximum density below a major source of pollution, bacteria of the types included both in the ordinary plate count and in the *B. coli* group tend to diminish in numbers progressively along a fairly well defined time-function curve, which follows closely a logarithmic path in its earlier stages, but tends to become increasingly flatter than such a path after passing through its initial phase. The proportionate rate of bacterial decrease is further modified by the temperature and other changes associated with seasonal cycles, the rate being higher in summer than in winter.

In Figure 1 are shown two bacterial reduction curves derived from *B. coli* observations[10] made in the Ohio River below Cincinnati, one curve being based on summer and the other on winter conditions. In each instance the curve has its initial point at the maximum density of *B. coli* attained in the river immediately below Cincinnati. On comparing the two curves it will be noted that the percentage of

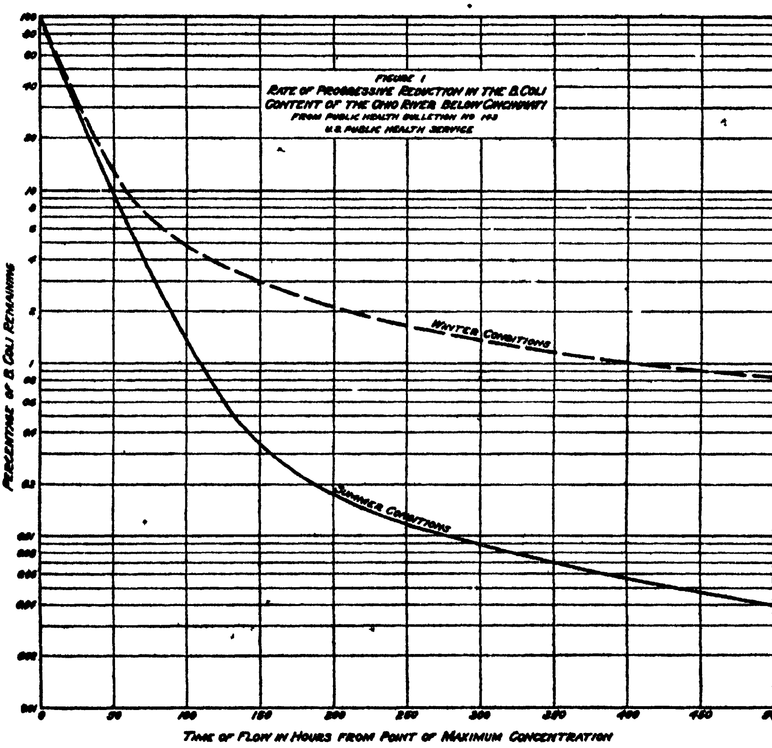
[10] Public Health Bulletin No. 143, U. S. Public Health Service. Tables 38 and 43.

initial *B. coli* density remaining after a mean time of flow equivalent to 100 hours is approximately 4.7 per cent under winter conditions and 1.5 per cent under summer conditions. For shorter times, the two residual percentages fall more closely together and for longer times diverge more widely from each other.

The relative effect at a given point in a stream of bacterial pollution originating from population groups located at more or less distant points upstream would be expected, on this basis, to be considerably greater under winter than summer conditions, all other things being equal. The converse may be true, however, of the



effect of pollution originating at more near-by sources, owing to lower stream flow and to the greater per capita contribution of sewage bacteria during the summer, both of which factors may offset the higher rate of natural purification in its earlier stages. The same general principle should hold with respect to the pollution of quiescent and semiquiescent bodies of water, when considered in reference to the times of passage of water between various sources of pollution and points at which water supplies are taken.

An illustration of the application of these principles is found in a calculation made of the relative effects of bacterial pollution derived from sewered population groups draining into the Ohio River and its

tributaries in successive 50-mile zones by water above the Cincinnati and Louisville intakes, respectively, during the summer and winter seasons of the year 1915.[11] In making this calculation the actual sewered population draining into each successive zone was tabulated, as shown in Table 1, together with the estimated mean time of flow of the river from the mid-point of each zone to the respective intake. By applying to each zone population a reduction factor represented by the percentage of *B. coli* remaining after the given time of flow, as shown in Figure 1, a series of "calculated equivalent" population figures was obtained representing, in each instance, the population which, if discharging sewage immediately above the intake, would have the same pollution effect at this point as did the actual corresponding population located in the particular upstream zone, under the seasonal and flow condition specified.

TABLE 1.[a]—*Actual sewered populations draining into the Ohio River and its tributaries in successive 50-mile zones, by water, above the Cincinnati and Louisville water intakes, respectively, together with their corresponding calculated equivalents with respect to the total bacterial pollution, in terms of B. coli, at each intake*

[a] Data transcribed from Public Health Bulletin No. 143, Tables Nos. 133, 134, 137, and 138.

[11] The data for this calculation have been derived from Public Health Bulletin No. 143, Tables Nos. 133, 134, 137, and 138, pp. 329-334.

A comparison of the percentages of the total actual population located in each zone with the corresponding percentages which their "calculated equivalents" are of their respective totals, provides an index of the relative effects which the various population groups

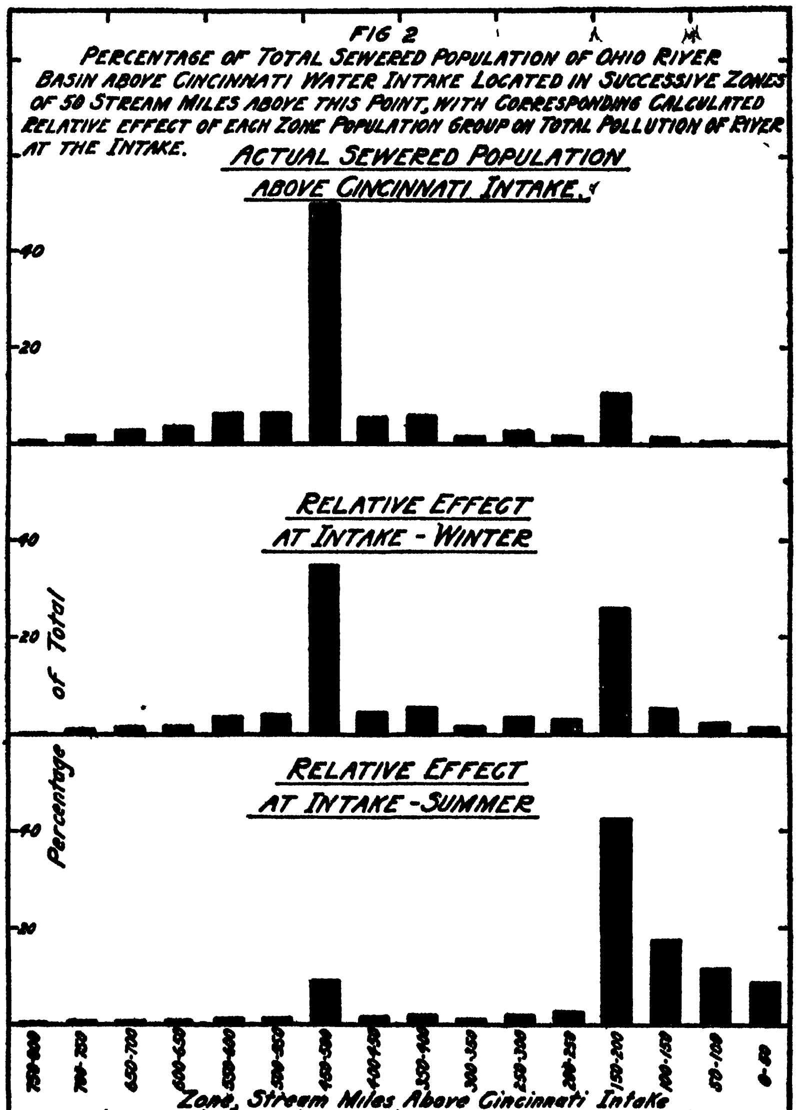

FIG 2
Percentage of Total Sewered Population of Ohio River Basin above Cincinnati Water Intake Located in Successive Zones of 50 Stream Miles above this Point, with Corresponding Calculated Relative Effect of each Zone Population Group on Total Pollution of River at the Intake.

were estimated as exerting on the pollution of the river at each one of the two intakes. The comparison is illustrated graphically in Figures 2 and 3, referring, respectively, to pollution conditions at the Cincinnati and Louisville intakes. In Figure 2, the effect of bacterial

pollution originating in the 50-mile zone located 450 to 500 miles above the Cincinnati intake, which includes the Pittsburgh metropolitan district, is indicated as being about 35 per cent of the total during the winter and only 9 per cent in the summer, when approxi-

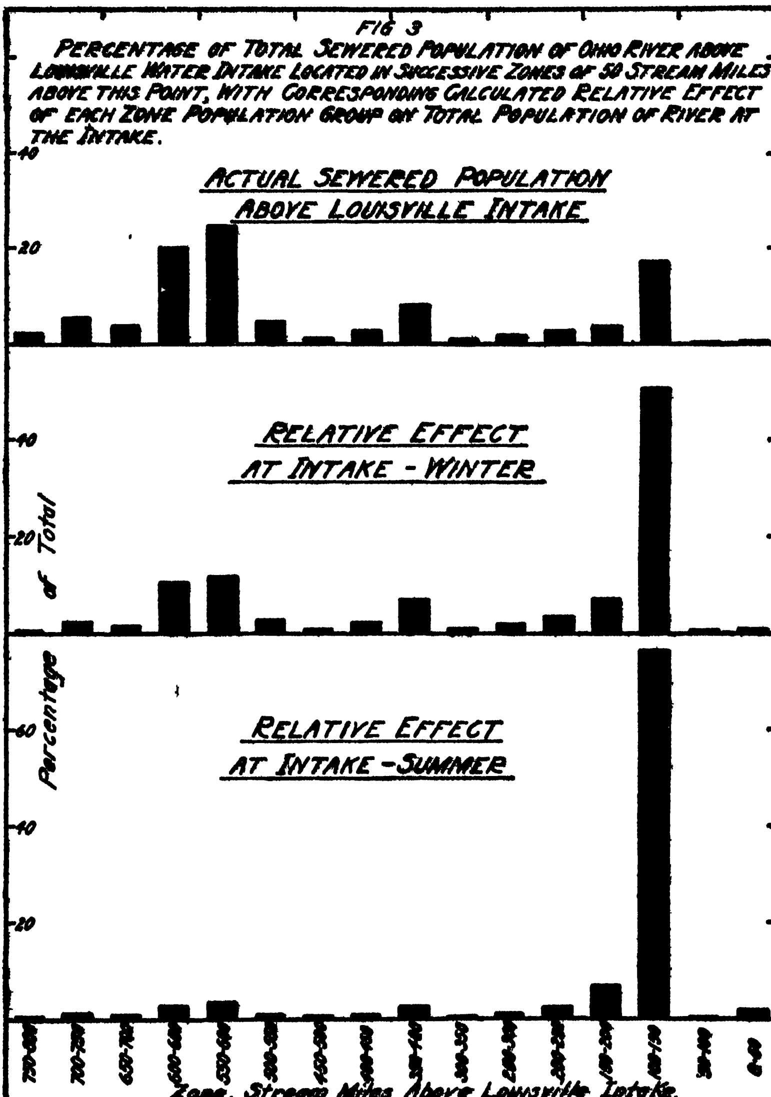

FIG 3
PERCENTAGE OF TOTAL SEWERED POPULATION OF OHIO RIVER ABOVE LOUISVILLE WATER INTAKE LOCATED IN SUCCESSIVE ZONES OF 50 STREAM MILES ABOVE THIS POINT, WITH CORRESPONDING CALCULATED RELATIVE EFFECT OF EACH ZONE POPULATION GROUP ON TOTAL POPULATION OF RIVER AT THE INTAKE.

mately 70 per cent of the total bacterial pollution at the intake is indicated as having been derived from zones lying within 200 miles above the intake. In Figure 3, sewage from the Cincinnati district and from Dayton, Hamilton, and other communities located in the

zone 100–150 miles above the Louisville intake is shown as being responsible for a large proportion of the pollution of the river at this point, both in winter and in summer. In this instance the relative effect of pollution derived from the Pittsburgh district (zones 550–600 and 600–650 miles) is small, even in the winter.

The illustrative examples above cited indicate, first, that in any appraisal of conditions of bacterial pollution surrounding a given source of water supply, full account should be taken not only of the relative sizes of the various population groups jointly responsible for the particular conditions at that source, but also of their respective locations, on a time-distance basis, with respect to the source in question. They further indicate that in any systematic stream-cleaning measures designed to protect sources of water supply, primary consideration should be given to sewage derived from population groups located in zones extending immediately above a given intake. Finally, they afford evidence that conditions of bacterial pollution occurring in streams during the winter season, when natural purification agencies are less active, may impose a more severe burden on sources of water supply than those prevailing during the summer season, as is shown by a comparison of the corresponding "equivalent population" figures given in Table No. 1. In this respect, the situation is quite the reverse of that which usually holds where the other aspects of stream pollution are concerned.

Having thus considered briefly some of the more significant elements involved in the bacterial pollution of surface sources of water supply and the extent to which it may be modified by natural agencies, it is proposed now to discuss the degree to which the effects of such pollution may be further offset by artificial methods.

EXTENT OF PROTECTION AFFORDED BY ARTIFICIAL PROCESSES OF WATER PURIFICATION

The extent of sanitary protection to water supplies of surface origin afforded by artificial processes of water purification may be said to depend primarily on the limitations of such processes with respect to their bacterial efficiency. Owing to the progressive advancement which has been and is occurring in the art of water purification, these limitations can hardly be regarded as being static; nevertheless they now appear to be sufficiently well defined to be capable of approximate determination for practical purposes.

In spite of the high degree of efficiency to which water purification has been developed, both in this country and in other countries, experience has shown that none of the processes involved in large-scale operations of this kind ordinarily are capable of removing from a bacterially polluted water all of the living organisms present in it. This is true not only of sedimentation and filtration processes,

aided or unaided by coagulation, but also, under normal conditions of practice, of those processes of chemical disinfection, such as chlorination, which have become such important adjuncts of modern filtration plants.

During the past few years a systematic effort has been made by the Public Health Service to determine, by combined observation and experiment, the nature and extent of the limitations above noted. These studies have had as their primary object the establishment of a basis for formulating, in specific physical and bacteriological terms, permissible limits of pollution of raw water supplies taken for purification from sewage-polluted sources of various classes, particularly in the inland navigable waters of the country on which large and important sections of the population are dependent for their public drinking-water supplies.

From these studies, which at the present writing still are in progress, a number of interesting conclusions of considerable practical significance have been drawn. Without entering into a detailed discussion of them here,[12] it is pertinent to note briefly the more significant conclusions thus far reached from them concerning the limitations surrounding the bacterial efficiency of water purification.

In general, the studies have shown that the efficiency of each separate process involved in water purification, such as, for example, coagulation, sedimentation, filtration, and chemical disinfection, is influenced by a number of factors, some of which are, and some are not, subject to physical control. Among the former may be noted the various conditions of plant design, such as retention periods provided in basins and depths and sizes of filtering material; likewise certain measures of operation, such as the amounts of coagulants and disinfectants used, the pH of the chemical reactions, and the rate of filtration. Among the latter are seasonal changes, notably those of temperature, and variations in the turbidity and bacterial content of the raw water.

More specifically, the studies have indicated that the average well-designed and well-operated rapid sand filtration plant, treating river waters such as are found in the Ohio and other river basins of the great Middle-Western plains, is capable of producing, with a fair degree of consistency, a final chlorinated effluent of acceptable palatability and conforming to the revised United States Treasury Department standard,[13] if the *B. coli* index of the raw water does not

[12] For such a discussion, see Public Health Reoprts March 31, 1922 (Reprint No 737), Jan 30, 1925 (Reprint No 987), Oct 1, 1926 (Reprint No 1114), July 15, 1927 (Reprint No 1170), also Public Health Bulletin No 172, U. S. Public Health Service

[13] The original Treasury Department standard, adopted in 1914 (Public Health Reports, vol 29, No 45, Nov 6, 1914, Reprint No 232) specified, in effect, that water served for drinking purposes by the interstate carriers should not contain numbers of *B coli* exceeding 2 per 100 cubic centimeters, as expressed in terms of the *B. coli* index The revised standard, adopted in 1925 (Public Health Reports, vol 40, No 15, Apr. 10, 1925, Reprint No. 1029) provides that the average *B. coli* index shall not exceed 1 per 100 cubic centimeters.

exceed approximately 5,000 per 100 cubic centimeters. A preliminary survey, now in progress, of a group of water-purification plants located along the Great Lakes has indicated thus far, however, that the average plant treating raw waters derived from these lakes can not produce consistently a final effluent of acceptable palatability and meeting the same standard of bacterial quality if the *B. coli* index of the raw water exceeds an amount falling somewhere below 2,000 per 100 cubic centimeters.

The extent to which modern water filtration plants treating surface waters from sewage-polluted sources are now dependent on continuous and effective chlorination of their effluents in order to produce drinking waters of acceptable bacterial quality is shown by the results obtained, in connection with these studies, from systematic observations of the quality of unchlorinated filter effluents as related to that of the various raw-water supplies. These observations have indicated, for example, that under the most favorable conditions thus far met in practice, the average water filtration plant treating river waters of the type above noted can not produce consistently an unchlorinated effluent conforming to the Treasury Department standard if the *B. coli* index of the raw water exceeds 60 to 100 per 100 cubic centimeters. In so far as plants treating Great Lakes waters are concerned, the corresponding average limit appears to fall somewhere less than 10 per 100 cubic centimeters.

Although the limits above stated are observational and, in the former instance, provide no working factor of safety, they may be regarded tentatively as representing the extreme limits of pollution of raw water supplies derived from the two respective types of sources named, which thus far have appeared to be most nearly consistent with the production, by the average plant, of effluents meeting a commonly accepted standard of bacterial quality under the particular conditions noted. These maxima may be said, therefore, to provide an approximate basis for judgment as to the suitability of sewage-polluted sources of water intended for purification to the respective degrees named.

It is especially worthy of note, in this connection, that for some reason or reasons not as yet fully determined, the bacterial efficiency of filtration plants treating raw waters such as are derived from the Great Lakes appears to be of a decidedly lower order of magnitude than that of similar plants treating river waters such as are found in the Ohio and other inland river basins lying east of the Mississippi.[14] If further observations now in progress should confirm this finding, it would appear logical to expect that any standard of bacterial pollution applicable to sources of purified water supplies located along the Great Lakes necessarily would be more rigid in its limiting require-

[14] No systematic observations thus far have been made west of the Mississippi River.

ments than would be a corresponding standard with respect to river waters of the Ohio type. In this connection reference should be made to the standard of raw water pollution set up by the International Joint Commission, in 1914, with respect to Great Lakes waters, the standard requiring, in effect, that the *B. coli* index of these waters, as delivered to purification plants for treatment, should not exceed 500 per 100 cubic centimeters.[15] Taking into account the factors of safety necessary to protect water purification plants treating waters of the Great Lakes from the effects of sudden and excessive variations in their bacterial content resulting from conditions somewhat peculiar to these waters in zones affected by shore pollution, the International Joint Commission standard would appear, from present indications, as being not far from that which ultimately may be found to be a reasonable one for such lake waters, though it probably is more rigid than is necessary for application to river waters of the Ohio River type.

SUPPLEMENTARY MEASURES FOR REINFORCING THE PROTECTION AFFORDED BY EXISTING WATER PURIFICATION SYSTEMS

The supplementary measures available for reinforcing the protection afforded by existing systems of water purification are of two general classes:

(1) Further elaboration of current water-purification processes; and

(2) Treatment of sewage and other wastes at their sources.

These measures are theoretically feasible to almost any desired degree. Practically, however, they are limited by a number of considerations, including those of economy. Let us consider, first, the further elaboration of current water-purification processes.

During the past three decades methods of water purification as practiced in the United States have undergone a steady course of improvement and of adaptation to the diversity of conditions existing in this country. In spite of their variations in respect to details, these methods have remained, however, substantially as they were at the time of Fuller's experiments at Louisville and Cincinnati in the late nineties. In New England and a few other limited areas of the country the English slow sand filter has proved satisfactory for the treatment of the relatively clear upland waters of these sections. Throughout the remainder of the country, including by far the greater portion, the rapid sand filtration process has been found best adapted to the purification of the variable and highly turbid river waters found in these extensive regions. The latter method, therefore, may be regarded as the more representative of current practice in the United States.

[15] Final report of the International Joint Commission on the Pollution of International Boundary Waters Reference 1918.

In its ordinary and more simple development the rapid sand filtration system provides facilities (*a*) for coagulating the raw water, (*b*) for subjecting it to a single stage of sedimentation after coagulation, (*c*) for passing it through rapid sand filters after sedimentation, and (*d*) for chlorinating it either before or after filtration.

Various elaborations of these ordinary water purification processes are being practiced, both in this country and abroad, with a considerable measure of success. Among the more important of these measures are—

(1) Long-time preliminary storage;

(2) Double-stage preliminary sedimentation, aided, in some instances, by two-stage coagulation;

(3) Double filtration;

(4) Prechlorination of the raw water, prior to its delivery to preliminary sedimentation basins.

In general, prolonged storage of sewage-polluted surface waters as a preliminary step in their more complete purification by filtration has not been adopted in the United States to the extent that it is practiced in Europe, notably in Great Britain. An important reason is the existence of unfavorable topography found along the relatively flat plains of many of our inland rivers and lakes, where the difficulties and cost of constructing storage reservoirs of large capacity are great. Although numerous stored water supplies are found in the mountainous sections of the Appalachian and Pacific coastal ranges, as a rule they are derived from relatively unpolluted upland sources and require little or no further treatment. Aside from a very few instances, notably at Albany, N. Y., double filtration, likewise, has had less use in this country than abroad, largely because of the added costs of treatment entailed by the added operating head required by this method.

Mainly for the reasons above noted, elaboration of the more simple types of filtration plants in the United States, when undertaken principally as a measure of offsetting increased raw water pollution, has had a tendency toward the extension of sedimentation devices and the intensification of chemical treatment. Along the Ohio River, for example, five municipal filtration plants now are equipped with double-stage sedimentation basins, aided, in three instances, by coagulation at both stages of treatment. At the new filtration plant located at Springfield, Ill., a mechanical clarifying device has been installed in advance of sedimentation. At three filtration plants located along the Great Lakes and at a few river plants treating highly polluted waters, prechlorination of the raw water prior to its treatment by coagulation, sedimentation, and filtration is being tested. Mention also should be made of the intensification of lime treatment

(commonly termed the "excess-lime" method) which is being practiced at a number of large water-softening plants and at a few plants devoted more strictly to water purification without softening.

In so far as can be judged from observational and experimental data now at hand, the elaboration of water filtration plants along the two lines last indicated above has resulted in extending very decidedly the permissible limits of raw water pollution, consistent with the production of effluents having a satisfactory bacterial quality, though in some instances, at the expense of their palatability, where the chemical treatment is too greatly intensified. Observations made at the five Ohio River plants, using double-stage preliminary sedimentation, have indicated that, as an average, they are capable of producing final chlorinated effluents conforming to the Treasury Department *B. coli* standard from raw river water having a *B. coli* index ranging as high as about 50,000 per 100 cubic centimeters. Although data concerning the corresponding efficiency of raw water prechlorination are too meager at present to warrant drawing any definite conclusions from them, they appear to indicate that this measure, when added to complete sedimentation and filtration treatment, can be made to yield a final effluent of satisfactory bacterial quality from raw river water having a *B. coli* index ranging as high as 10,000 or even 20,000 per 100 cubic centimeters.

The cost of these various added measures of water treatment is a factor, however, to which an increasing amount of attention probably will be given as sources of surface water supply become more highly polluted and recourse necessarily is had to such measures. In a recent paper,[16] Hansen states that the ordinary water purification system will cost up to $4 or $4.50 per capita, and the most highly elaborated plant up to $10 per capita. He gives the annual cost of purification as being usually less than 85 cents per capita.

In this connection, some interesting data bearing on the relation between the cost of water purification and the average density of raw water pollution have been obtained from surveys of a group of municipal water purification plants made during the past few years by investigators of the Public Health Service. In Table 2 is given a tabulation of the costs of operation of 10 municipal water filtration plants from which fairly complete data in this respect were secured. In order to reduce the costs to a comparable basis, they have been calculated to terms of the cost per million gallons of water treated and of the annual cost per capita.

[1] Average for three years, 1924, 1925, 1926.
[2] Affected by abnormal conditions, therefore omitted.
[3] Included pumping costs which could not be separated, therefore omitted.
[4] Raw water relatively clear, comparatively small amounts of coagulants used. Omitted from plot in Fig. 6.

In Figure 4, plotted from the data contained in Table 2, is shown graphically the relation observed between the annual average density of raw water pollution expressed in terms of the *B. coli* index, and the cost of chemical treatment per million gallons of water treated. It will be noted that, for a given degree of raw water pollution, this cost is slightly less at plants equipped with double-stage sedimentation than at plants having only single-stage sedimentation. Against this advantage, however, should be balanced the added cost, in the former instance, of constructing and operating the extra basins necessary to provide the two separate stages of sedimentation.

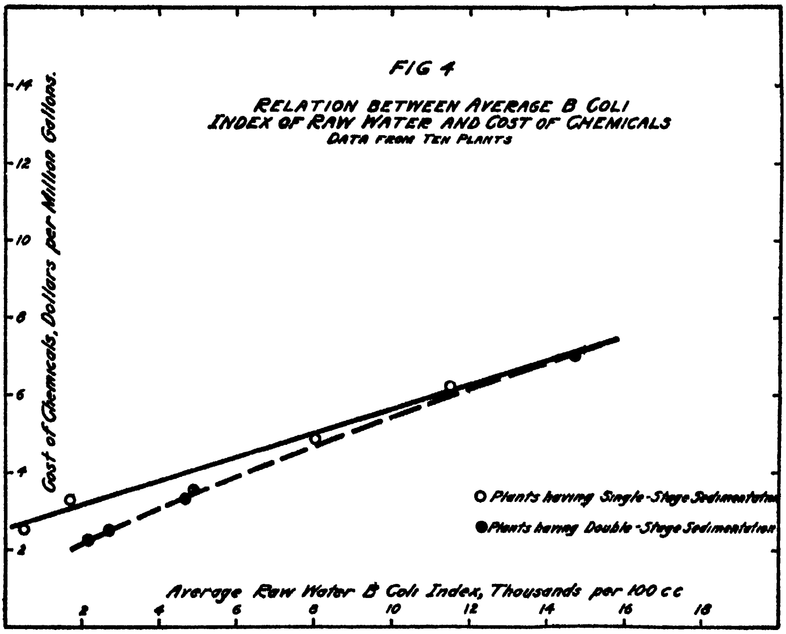
In Figure 5, also derived from Table 2, is shown the corresponding relation observed between the density of raw water pollution and the total cost of operation, which is indicated as ranging from about $5 to $20 per million gallons coincidently with a raw water *B. coli* index varying, as an extreme range, from 1,000 to 16,000 per 100 cubic centimeters. The graphs shown in Figures 4 and 5 indicate that for each successive increase of 1,000 in the average raw water *B. coli* index the total cost of purification is increased by approximately $1 per million gallons, and the cost of chemical treatment by about 30 cents per million gallons. These figures do not include the cost of pumping or any fixed charges against construction. From the figures given by Hansen, the latter would be expected, at 6 per cent, to range from 24 to 60 cents per capita annually, or from about $6 to $16 per million gallons of water treated, depending on the extent of elaboration of the plant.

By combining the fixed and operating costs above given, it may be estimated very roughly that the total cost of water purification, including construction and operation, may vary, in round numbers, from about \$10 to \$35 per million gallons, or from about \$0.40 to \$1.40 per capita per year, according to the degree of pollution of the raw water and the extent of plant elaboration required. Although the upper limiting figure of this range represents a degree of raw water pollution thus far encountered by relatively few water purification plants in this country, the difference between the two limiting figures, amounting to \$1 per capita annually, is significant as indicating the extent by which an extreme condition of this kind, where prevalent, may increase the total cost of water purification over and

FIG 4

RELATION BETWEEN AVERAGE B COLI INDEX OF RAW WATER AND COST OF CHEMICALS

DATA FROM TEN PLANTS



above that which is required for treating a moderately polluted water. It may be said, in fact, to represent approximately the added tax which an excessive pollution of sources of raw water supply, if allowed to become increased to an extent such as now prevails in portions of our more highly polluted river systems, may be expected to impose on the consumers of purified water supplies derived from such sources.

Sewage treatment measures.—The use of sewage treatment as a specific measure for protecting sources of water supply has been regarded, with justification, as being necessarily secondary to that of water purification, for reasons which are well known to all students of the problem as it has developed in this country. With the increasing pollution of our large river systems and the possible over-

burdening of some of the more highly elaborated water purification plants, more consideration may be expected to be given to this measure than heretofore has been necessary.

In this connection, a number of questions arise, among which two are of primary importance: First, What general method of sewage treatment may be regarded as affording adequate protection to sources of water supply? Second, What is the relative cost of such treatment, in comparison with the cost of other measures which may be utilized for relieving the overburdening of existing water-purification plants?

As regards the first of these two questions, opinions appear to differ. In England, where the streams are short and small in volume,

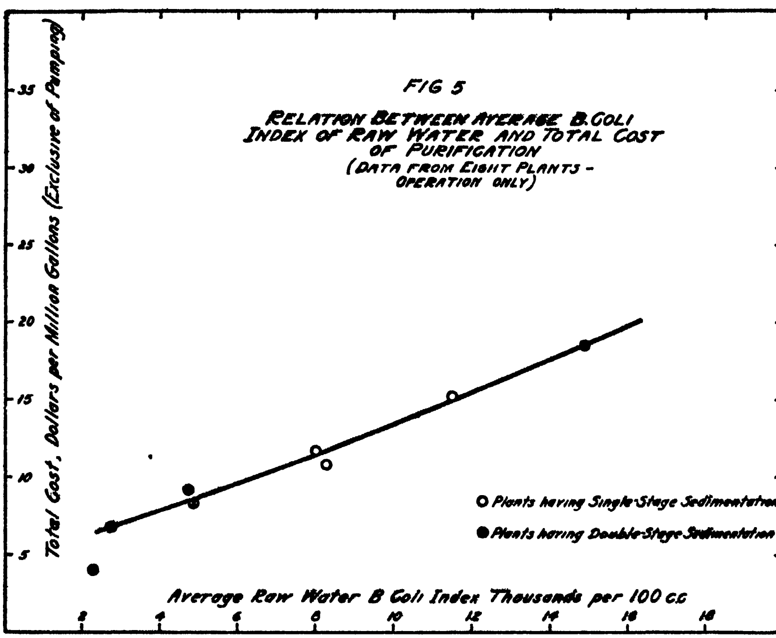


FIG 5

RELATION BETWEEN AVERAGE B. COLI INDEX OF RAW WATER AND TOTAL COST OF PURIFICATION (DATA FROM EIGHT PLANTS - OPERATION ONLY)

the view seems to prevail that nothing short of complete treatment of sewage, including its clarification, oxidation, and bacterial disinfection, may be considered as adequate for water-supply protection. In this country, partial clarification and disinfection have been advocated as being ordinarily sufficient, on the assumption that the treatment of sewage to this extent will render it bacterially innocuous and that more extensive purification is required only where the natural oxidation capacity of a stream is overtaxed. Superficially, the latter procedure would seem to be a reasonable one under most of the conditions prevailing in the United States, where the rivers are relatively long, are large in volume and, in a number of cases, possess an ample capacity for natural oxidation of sewage matters. On the other hand, it must be admitted that comparatively little

scientific information exists in this country as to the efficacy of partial sewage treatment when practiced solely as a measure for water-supply protection.

As regards the cost of complete sewage treatment, Hansen [17] has stated recently that the annual cost would average approximately 95 cents per capita, exclusive of the cost of necessary intercepting sewers, which would range from $1 to $10 per capita per year. From cost statistics [18] from a group of representative American sewage treatment plants, as given by Wagenhals, Theriault, and Hommon, it has been estimated that if the costs as given were corrected to a basis of the year 1924, the average total annual cost of treatment, including fixed and operation charges, would be about 90 cents per capita, which figure corresponds closely to that given by Hansen. (See Table 3.) With the cost of intercepting sewers excluded, the balance of cost as between complete sewage treatment and water purification would appear to be about equal where the more highly elaborated types of the latter are concerned, but to favor the latter in its more simple forms as ordinarily practiced. With intercepting sewers included, the balance clearly favors water purification, regardless of its degree of elaboration. Where highly elaborated water purification plants are overburdened, and the only remaining alternatives are sewage treatment or preliminary storage of the raw water at the intake, the relative costs of these two measures will be the determining factor.

TABLE 3.—*Per capita costs of sewage treatment, both as of date and corrected to the year 1924, as indicated by data from 11 representative sewage-treatment plants in the United States*

[Compiled from data given in Public Health Bulletin No. 132, U. S. Public Health Service]

Plant	Year constructed	Cost per capita							Factors	
		Construction				Operation (annual)		Total as of 1924 (4)+(6)	Construction [a]	Operation [b]
		Initial		Annual, at 6 per cent		1919–1920	As of 1924

[18] Wagenhals, H. H., Theriault, E. J., and Hommon, H. B.: Sewage Treatment in the United States. Public Health Bulletin No. 132, U. S. Public Health Service.

In the foregoing estimates, a relatively complete degree of sewage treatment has been assumed. If such treatment were restricted to fine screening, or plain sedimentation, and chlorination, such as is commonly practiced for the protection of bathing beaches, the cost of sewage treatment would be correspondingly lowered. Thus, the cost of fine screening and chlorination combined may be estimated very roughly as being about $10 per million gallons of sewage treated or about 40 cents per capita annually. If this figure were used as the basis of comparison, the cost of such partial sewage treatment would appear to be practically the same as that of the more simple types of water purification. If the added cost of intercepting sewers were included, the balance again would favor water purification as being the more economical.

In estimating the extent of sewage treatment required in order to effect a specified degree of reduction in the average bacterial pollution of a stream at a given source of water supply, an analysis of the problem along lines such as are indicated in Table 1 and Figures 2 and 3 may be helpful. Let it be assumed, for example, that it were desired to reduce the average bacterial pollution of the Ohio River at the Louisville water intake by sewage treatment applied to population groups located in zones above that point. On referring to Table 1 it will be noted that the relative influence on the *B. coli* content of the river at Louisville exerted by sewered population groups located in the zones lying within 200 stream miles above that point was 58.7 per cent of the total under winter conditions and 85.2 per cent of the total under summer conditions such as prevailed in the year 1915, as is indicated by the percentages of the total "calculated equivalent" population effective at this point. If all of the sewage of this population, aggregating 654,800, were given treatment such as to cause a 90 per cent reduction in its *B. coli* content, the average density of *B. coli* at the Louisville intake, attributable to domestic sewage discharged into the river above that point, would be expected, on this basis, to be diminished by 0.90×58.7 per cent, or 53 per cent, under winter conditions, and by 0.90×85.2 per cent, or 77 per cent, under summer conditions. Under the more unfavorable winter condition, therefore, a reduction approximating one-half the total sewage pollution of the river at the Louisville intake, as expressed in terms of *B. coli*, would be expected to result from effective sewage treatment applied within the restricted zone specified. In this connection it is also significant to note that, on the basis of the percentages given in Table 1, equally effective treatment of all the sewage discharged into the Ohio River by the 1,378,100 of sewered population located in the two zones, 550–600 miles and 600–650 miles, in which the Pittsburgh district is included,

would be expected to reduce the average *B. coli* content of the river at Louisville by less than 20 per cent under the winter conditions of 1915 and by less than 6 per cent under summer conditions.

The foregoing illustration, though it should not be interpreted too literally as regards the actual figures obtained from the calculation, is instructive in showing that systematic stream-cleaning measures, if undertaken primarily for the protection of water supplies, may be applied with a considerable degree of economy if a thorough study is made of the comparative influence of wastes derived from various population groups, when considered in their time-distance relationships to the sources of such supplies. It is further significant as indicating a fairly simple method, in specific cases, for balancing the total cost of stream-cleaning measures against that of additional water purification, where practicable. In the instance above cited, for example, the cost of sewage treatment as applied to a sewered population aggregating 654,800 would be balanced against the cost of added water purification as applied to the population of Louisville, which in 1915 was estimated as being about 308,000. In this case, the balance clearly would favor added measures of water purification up to a point such that their per capita cost would be slightly more than double that of sewage treatment.

CONCLUSION

In concluding this paper it may be well to note very briefly the present status, in this country, of the general problem with which it has been concerned.

The excessive sewage pollution of surface bodies of water used as sources of water supply has begun to attain serious proportions in certain areas of the eastern and middle-western States, notably in the Ohio and Hudson River basins, and in some marginal zones of the Great Lakes, particularly at a few points located along Lake Erie, in the extreme southern end of Lake Michigan, and in some of the connecting waters as in the Detroit and Niagara Rivers. In portions of these areas water purification plants have been and are being elaborated more and more in an effort to offset increased raw water pollution. In some instances, recourse either to additional water storage or to sewage treatment measures probably will be necessary in the not distant future. In certain cases the presence of industrial wastes in sources of raw water supply is a further complicating factor, especially in the upper portions of the Ohio River and at some points along the Great Lakes.

Although isolated instances of excessive pollution, such as above mentioned, are found in other sections of the country, the situation in these areas is, in general, such that existing water purification

systems, where properly designed and efficiently operated, are not overburdened. In these regions systematic measures for preventing any widespread overloading of water purification plants can readily be taken and, in some cases, notably in North Carolina, are being actively considered by the State health authorities.

The effectiveness of measures for relieving or preventing the excessive pollution of water-supply sources will involve, however, not only a thorough knowledge of the technical phases of the problem, some of which have been discussed in this paper, but also the provision of an adequate and well coordinated administrative machinery, backed, where necessary, by intelligent legislation. Thus far, efforts to set up such a machinery have been hampered, to some extent, by a lack of the necessary technical groundwork, and further by the fact that the problem, in many cases, transcends State and even international boundaries. Studies such as are being made by the Public Health Service and other agencies are being aimed to evaluate the more essential technical factors involved in the problem. On the administrative side, an interesting experiment is being made by the States bordering the Ohio River in forming an interstate association with a view to coordinating the legislative and regulatory policies of these several States in dealing with stream pollution matters. In another case, an effort is being made to solve this question by interstate treaty. Within some States, sanitary districts are being organized for the purpose of effecting a well-coordinated joint solution of existing problems of water supply and sewage disposal.

The several activities thus noted, together with others of a similar nature, appear to give promise that a wise solution of these problems ultimately will be found. Further technical studies are needed, especially those concerned with the economic phases of the question, which are becoming increasingly important. There also remains the difficult problem of dealing with the excessive pollution of water supplies by industrial wastes, with its baffling technical and administrative aspects. In spite of these and numerous other unanswered questions, these matters can be faced with the renewed assurance bestowed by an awakened public interest in the conservation of our water resources and by the support which efforts to meet the problem are receiving both from the public at large and from various professional organizations. These resources are indeed our greatest national asset, indispensable both to our industrial development and to the continued health and happiness of our population. If unduly neglected, they may well become our greatest liability.

COURT DECISIONS RELATING TO PUBLIC HEALTH

Enforcement of laundry ordinance not enjoined.—(Illinois Supreme Court; Ruban et al. *v.* City of Chicago et al., 161 N. E. 133; decided April 21, 1928.) Suit was brought by the plaintiffs to restrain the city of Chicago from enforcing an ordinance regulating the laundry business. The plaintiffs received soiled clothes and linens, had the same collected, washed, dried, and returned by steam laundry companies, and then hand-ironed the articles themselves. The city ordinance provided that any place, etc., which was used for the purpose of washing, drying, starching, or ironing wearing apparel, linens, etc., for the general public should be deemed a laundry, and required a license to conduct the same. The court held that the city had the power to direct the location and regulate the use and construction of laundries, and that the requirement of a license was legal. The plaintiffs contended that they were not engaged in the laundry business, the basis of their contention being that a laundry was a place where clothing and other articles were washed and ironed. But the court pointed out that the definition in the ordinance of a laundry, which definition it was held was a proper incident to the power conferred to regulate laundries, was that it was any place, etc., used for the purpose of marking, sorting, washing, drying, starching, or ironing the articles therein mentioned, and decided that the plaintiffs were engaged in the laundry business and were not entitled to the relief asked.

Recovery of damages for injuries from glass in milk denied.—(Massachusetts Supreme Judicial Court; Carlson *v.* Turner Centre System, 161 N. E. 245; decided April 5, 1928.) The plaintiff, who purchased a bottle of milk from a retail dealer, sought damages, for injuries from a small piece of glass in the milk, from the defendant corporation, which bottled and sold the milk to the retailer, in an action of contract on the ground of an implied warranty by the defendant that the milk was wholesome and fit for human consumption, but the supreme court denied recovery because there was no contractual relation between the defendant and the plaintiff, who had dealt only with the retailer.

Property owner personally liable for installation of sanitary toilet by city.—(Alabama Supreme Court; Town of Leeds *v.* Cason, 116 So. 519; decided April 14, 1928.) In an action by a municipality to recover the cost of installing a sanitary toilet on private property, upon failure of the owner to install same, as provided by an ordinance adopted pursuant to law, the court held that, although the city had failed to comply with the statutory provisions necessary to the enforcement of a lien on the property, there was a personal liability on the owner for the expense and that a contract action could be maintained.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Some of the Newer Industrial Hazards. Frederick B. Flinn. *The Boston Medical and Surgical Journal*, vol. 197, No. 28 January 12, 1928, pp. 1309–1314. (Abstract by R. R. Sayers.)

While toxicology is only one of the fields of preventive medicine, it is being considered of increasing importance as it is realized that perhaps exposure to industrial poisons may explain some of the obscure symptoms of which patients complain, but for which there is no apparent cause. It is known that many of the toxic substances are rendered harmless if the amount present in the air or dust can be kept below a certain maximum point. This can be done by proper methods of ventilation adapted to each particular hazard. It is the province of the medical man to determine the limits that can be tolerated by the human system, and that of the ventilating engineer to determine the methods of remedying the conditions.

Results are given of a study made by investigators of the United States Public Health Service among granite workers to determine whether or not a standard of dustiness could be set up as a maximum which might safely be considered as the limit for that industry. From the results of this study the conclusion is drawn that a certain amount of this dust is tolerated by the human system.

Lead is discussed as still being the most important industrial poison, with the exception of carbon monoxide. An analysis of 18 industries in which the most of the lead cases appear, shows that the precise cause of the incidence in all of them is the inhalation of either dust or fumes. If the dust and fumes should be completely eliminated, lead poisoning in the industries will be stopped. The statement is made that the suspicion seems justified at the present moment that a change in the hydrogen ion of a cell affects its affinity for lead, and the author is not willing to place all the blame for cases of lead poisoning among persons addicted to alcohol or lack of personal cleanliness. The symptoms and pathological effects of lead poisoning are pointed out.

The danger of the use of benzol in quick-drying paints is pointed out but; on account of the hazard, benzol is being replaced by such substances as xylol. Acute cases of poisoning from benzol occur most frequently in industry either when the benzol is being prepared from coal tar or is used in concentrated form, as in the blending of motor oils or in the extraction of certain chemicals, where the very nature of the process requires that the operation be carried on in a closed system for economical if for no other reasons. The symptoms and pathological effects of benzol poisoning are described.

Attention is called to deaths occurring among workers employed in painting dials with luminous material. The symptoms of poisoning from this source and the pathological effects are described. Two main exposures in the industrial production and use of radium are described: (1) Exposure to the emanation which may result in radioactive deposits in the body or in external burns when the material is handled in a careless manner; and (2) the ingestion of the radioactive material, either by inhalation of the dust or by actually swallowing the material through ignorance or willfulness on the part of the employees.

Deaths from Lead Poisoning. Frederick L. Hoffman. Bulletin No. 426, United States Bureau of Labor Statistics, Washington, February, 1927. (Abstract by Leonard Greenburg.)

Lead continues to occupy a position of supreme importance as an industrial poison, and for this reason the present bulletin is of much interest and value. In this volume Doctor Hoffman has analyzed the available statistics of chronic lead poisoning in the United States, Canada, Great Britain, and certain other foreign countries. In addition to this, there is presented an analysis of deaths from

chronic lead poisoning in the United States registration area from 1914 to 1924. The death certificates for lead poisoning are further classified by occupation and age, and in certain cases statistics concerning contributory causes of death are presented and analyzed. Lastly, in part 3 of the bulletin, are presented the statistics for chronic lead poisoning from four State accident boards, namely, Massachusetts, Pennsylvania, California, and New York.

It is obviously quite impossible in a brief abstract to present Doctor Hoffman's findings in any detail. The death statistics of the United States registration area as well as those of the Metropolitan Life Insurance Co. show that the death rate has been declining since the year 1912, and now, according to these data, has reached the rate of 1.6 per 1,000,000 persons exposed. The rate for white males and for colored males appears to be very nearly the same.

The largest number of deaths took place in the occupational group of painters, and but 62 deaths occurred in the group of lead workers in smelting plants, etc.

The worker in the field of industrial hygiene can not fail to be interested in this report, and to those interested in the problem of lead poisoning it is of great value.

The Use of Ozone in the Ventilation of the Automobile Service Station. M. R. Mayers. Indust. Hyg. Bull. New York, 1927, v. 3, 37–38. (Abstract by P. S. Lelean in *Bulletin of Hygiene*, vol. 2, No. 12, December, 1927, p. 971.)

"The author gives the analysis of motor-car exhaust air as: Carbon dioxide, 8.6 per cent; carbon monoxide, 6.3 per cent; oxygen, 2.3 per cent; methane, 0.9 per cent; hydrogen, 3.0 per cent; nitrogen, 78.6 per cent.

"The carbon monoxide increases to 11 per cent in the exhaust-air of cars under test in garages in hot weather.

"Hence 54 per cent of garage air tested had over the 0.1 per cent of CO which is regarded as the danger limit in the United States, while 69 per cent of garage men had CO in their blood in amounts ranging from 2.3 to 40 per cent of saturation point, in association with reduction of oxygen from the normal of 19 vol. per cent to as low as 2.4.

"Dizziness, smarting of the eyes, nausea, drowsiness, and incoordination caused complaints and inefficiency; but the most marked effect, and the predominant cause of stopping work, was intense headache.

"As an antidote, firms have marketed 'ozonators' under the erroneous idea that the ozone will oxidize the carbon monoxide to dioxide. The garage men have, however, found so much reduction of headache to follow use of these "ozonators' that the cause is being investigated. It is provisionally attributed to (*a*) psychological effect, and (*b*) action of ozone in preventing the carbon monoxide from markedly reducing the partial pressure of oxygen in the alveolar air."

Municipal Developments at Noranda, Quebec. Alex. M. Hogg. *Canadian Engineer*, vol. 54, No. 3, January 17, 1928, pp. 135–137. (Abstract by R. E. Thompson.)

An illustrated description of the municipal activities at Noranda, Quebec, a town fostered by the Horne Copper Co., in connection with the smelter being erected at that point. The present town of Rouyn and the new town of Noranda are situated on the shore of a small lake, from which both towns derive their water supply and which is the only possible point of discharge for the sewage of Noranda. This situation demands, of course, complete treatment of the sewage. A narrow peninsula extending well out into the lake was selected as a site for both plants, the water supply being taken from one side of the peninsula and the sewage being discharged into the lake on the other side. There is a flow line of 2½ miles between the intake and the point of sewage discharge. The sewage plant is designed to deal ultimately with a flow of 1 m. g. d. and consists of coarse bar screens, a Dorrco screen, aeration units providing retention period of 6 to 8

hours, and a Dorr clarifier. The sludge return will be about 20 per cent. During storms, when the flow exceeds 1 m. g. d., the excess will be diverted into a Dorr clarifier before being discharged into the lake. This tank will also be employed for sludge digestion. The water purification process consists of coagulation, filtration, and chlorination. The air for backwashing the filters and for aerating the sewage will be provided by air compressors located in the pumping station of the water plant. The plant is of the mechanical gravity type, with an ultimate capacity of 1 m. g. d.

Activated Sludge Plant for Wahiawa, Territory of Hawaii. F. M. Veatch. *Engineering News-Record*, vol. 100, No. 12, March 22, 1928, pp. 478–480. (Abstract by C. R. Cox.)

Wahiawa, a village of 3,000 population, is located on the island of Oahu, about 23 miles from Honolulu, on the shores of a large irrigation reservoir. A site for a sewage treatment plant was not available unless sewage could be piped about 2 miles to a point below the dam of the reservoir, where complete treatment would be necessary owing to the practically negligible flow of the stream during parts of the year. The same degree of treatment would permit the discharge of the effluent into the reservoir, so the cost of the sewer was avoided by constructing the plant near the village on the shores of the reservoir. The sewage works are designed for a population of 6,000, assuming an estimated flow of 100 gallons per capita per day. The disposal plant will consist of plain settling tanks, mixing tank, aeration tank, final settling tanks, sludge digestion tanks, glass-covered sludge drying beds, chlorination tank, and the building which houses the blowers and sludge-pumping equipment. The preliminary settling tanks are designed with a detention period of 30 minutes and are fitted with hopper bottoms. They are designed for radial flow. Sludge will flow through suitable pipes to a sump, from which it will be pumped to the digestion tanks. Sewage flows from the preliminary settling tanks to the mixing tank, where 20 per cent return sludge is mixed by air agitation. Six aeration tanks are provided, with a detention period of six hours with 20 per cent return sludge. A single row of filtros plates are placed to one side of the center line of each tank to produce spiral flow. Short-circuiting is prevented by the use of two division walls provided with square ports. Two final settling tanks of the Dorr clarifier type are provided, each 20 feet in diameter and with 1 to 2 hour detention period. At periods of low water in the reservoir the settled effluent will be disinfected with liquid chlorine. A hopper-bottom tank with a capacity of 15 minutes will be provided for the chlorine reaction. Sludge from the chlorination tank will flow by gravity to the sludge sump. A sludge-digestion tank, with capacity of 2 cubic feet per capita, is provided. This tank will be divided into six compartments so that the total length of flow from inlet to outlet will be approximately 200 feet, thus preventing the undigested sludge from reaching the outlet. A gas-collecting dome is provided over the digestion tanks, and the water level will be maintained somewhat above the level of the scum to prevent caking. The supernatant liquid from the sludge-digestion tanks will be returned to the preliminary settling tank for retreatment. Provisions have been made for circulating the digesting sludge and for adjusting the pH of the sludge by the use of lime when necessary. Covered sludge drying beds with an area of ⅜ square foot per capita are provided.

A motor-driven diaphragm pump is used to pump activated sludge, and the sludge from the other tanks will be removed by centrifugal pumps. An air pressure of 4 pounds per square inch will be produced by 3 motor-driven rotary blowers, with capacities of 100, 200, and 300 cubic feet per minute, respectively, which is equivalent to 0.25, 0.5, 0.75 cubic foot per gallon of sewage. The cost of the plant will be $96,130.

The Industrial Waste Research Problem in Southern California. R. F. Goudey. *Western Construction News*, vol. 3, No. 1, January 10, 1928, pp. 18–20. (Abstract by E. A. Reinke.)

Southern California has about 5,000 industries, many of which have serious difficulties in disposing of liquid wastes. No streams are available for dilution and inland towns will be dependent on high-grade treatment with disposal on land or in dry stream beds.

Research in industrial wastes is a logical extension of research in sewage disposal. Factors of temperature, staleness of sewage reaching plants due to low grades or long travel, and variable quality of sewage constituents due to high fruit and vegetable diets, all tend to make the problem of sewage disposal different from that in the East. The industrial wastes are also different, and separate study must be made of each kind of waste.

The only practical solution of the problem seems to be to have a research organization either as a part of the department of public health, the department of natural resources or some other State department. Private engineers can not afford to carry on this kind of research; industries will not carry it on unless forced to do so; salesmen can only try out their equipment, which is not likely to bring about fundamental solutions; student theses are not sufficiently prolonged to allow a complete solution; and the various organizations now working intermittently are not equipped to handle the work adequately.

The Sewage Treatment Works at Delaware, Ohio. Wm. L. Havens. *The American City*, vol. 38, No. 3, March, 1928, pp, 78–80. (Abstract by C. R. Cox.)

Sewage treatment works consisting of septic tanks and contact beds, built in 1902, were neglected within five years, but no improvements were made until the recent construction of the new plants of the Imhoff trickling filter type. Sewage is passed through bar screens and then pumped by low-lift pumps with automatic controls. Two Imhoff tanks, with detention period of two hours, are provided with facilities for reversing with flow. Sludge is drawn by gravity. Two dosing tanks with twin siphons are provided to alternate the flow of sewage to the two trickling filters with total area of 0.55 acre, which provides a loading of 26,400 people per acre. The filter material consists of 7 feet of broken limestone with 1 foot of crushed granite. The granite is used to prevent disintegration. Nozzles are spaced 15 feet on centers. Underdrains are vitrified channel blocks on which vitrified supports for filtering material are laid. A Dorr clarifier with 45-minute period is used as humus tank. Covered sludge drying beds will be provided later. The per capita cost of the plant was $13.92.

DEATHS DURING WEEK ENDED JUNE 2, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended June 2, 1928, and corresponding week of 1927. (From the Weekly Health Index, June 6, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended June 2, 1928	Corresponding week, 1927
Policies in force	71, 296, 695	67, 837, 137
Number of death claims	12, 482	11, 089
Death claims per 1,000 policies in force, annual rate	9. 2	8. 5

Deaths from all causes in certain large cities of the United States during the week ended June 2, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, June 6, 1928, issued by the Bureau of the Census, Department of Commerce)

[1] Annual rate per 1,000 population.
[2] Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
[3] Data for 66 cities.
[4] Deaths for week ended Friday, June 1, 1928.
[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31; Baltimore, 15; Birmingham, 39; Dallas, 15; Fort Worth, 14; Houston, 25; Indianapolis, 11; Kansas City, Kans., 14; Knoxville, 15; Louisville, 17; Memphis, 38; Nashville, 30; New Orleans, 26; Richmond, 32; and Washington, D. C., 25.

Deaths from all causes in certain large cities of the United States during the week ended June 2, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, June 6, 1928, issued by the Bureau of the Census, Department of Commerce)—Continued

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

SUMMARY OF MONTHLY REPORTS FROM STATES

The following summary of monthly State reports is published weekly and covers only those States from which reports are received during the current week:

State	Meningococcus meningitis	Diphtheria	Influenza	Malaria	Measles	Pellagra	Poliomyelitis	Scarlet fever	Smallpox	Typhoid fever
April, 1928										
Hawaii Territory	6	31	8		18		0	4	0	12
Montana	15	23	168		30		2	87	105	2
Virginia	7	80	2,879	63	3,348	35	5	161	33	29
Washington	19	41	55		662		6	190	195	17
May, 1928										
Alabama	4	40	1,141	142	1,348	102	4	30	51	26

April, 1928

	Cases
Chicken pox:	
Hawaii Territory	49
Montana	71
Virginia	628
Washington	401
Conjunctivitis (follicular):	
Hawaii Territory	159
Dysentery:	
Virginia	50
German measles:	
Montana	4
Washington	37
Hookworm disease:	
Virginia	9
Impetigo contagiosa:	
Washington	16
Leprosy:	
Hawaii Territory	7
Lethargic encephalitis:	
Montana	1
Washington	4
Mumps:	
Hawaii Territory	30
Montana	7
Washington	368
Paratyphoid fever:	
Hawaii Territory	1
Rocky Mountain spotted or tick fever:	
Montana	4
Washington	1
Scabies	
Washington	6
Trachoma	
Hawaii Territory	160
Montana	1
Whooping cough:	
Hawaii Territory	2
Montana	42
Virginia	500
Washington	61

May, 1928

	Cases
Alabama:	
Chicken pox	156
Dengue	2
Lethargic encephalitis	4
Mumps	89
Whooping cough	107

PLAGUE-PREVENTION WORK IN THE UNITED STATES

California.—The weekly reports of plague-suppressive measures in California during the 10 weeks from March 11 to May 19, 1928, show a total of 7,968 rodents received and 6,728 examined during the period. None was reported plague infected. The last rodent infection reported was six ground squirrels February 25–28, 1928, in Santa Cruz, Calif. The last case of human plague was reported as occurring on February 9, 1928, also in Santa Cruz, Calif.

Los Angeles, Calif.—The rodent division of the Los Angeles Board of Health reports 8,485 rodents collected and 4,767 examined during the nine weeks from March 18 to May 19, 1928. None was found plague infected.

Seattle, Wash.—The report of rat-trapping operations at Seattle for the months of March and April, 1928, show a total of 2,460 rodents taken and 1,197 examined during the two months. None was found plague infected.

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 100 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,570,000. The estimated population of the 95 cities reporting deaths is more than 30,960,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended May 26, 1928, and May 28, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
41 States	1,351	1,567	
100 cities	778	1,016	841
Measles:			
39 States	16,597	10,807	
100 cities	7,900	3,225	
Poliomyelitis:			
41 States	27	21	
Scarlet fever:			
41 States	3,424	3,777	
100 cities	1,416	1,747	1,118
Smallpox:			
41 States	822	637	
100 cities	105	170	110
Typhoid fever:			
41 States	282	407	
100 cities	50	56	63
Deaths reported			
Influenza and pneumonia:			
95 cities	1,187	633	
Smallpox:			
95 cities	0	0	

City reports for week ended May 26, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population, July 1, 1926, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported
			Cases, estimated expectancy	Cases reported	Cases reported	Deaths reported

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended May 26, 1928, compared with those for a like period ended May 28, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1928 and 1927, respectively, authoritative figures for many of the

cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,657,000 in 1928 and 31,050,000 in 1927. The 95 cities reporting deaths had nearly 30,961,000 estimated population in 1928 and nearly 30,370,000 in 1927. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, April 22 to May 26, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

THE FAR EAST

Report for the week ended May 19, 1928.—The following report for the week ended May 19, 1928, was transmitted by the Eastern Bureau of the Health Section of the Secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Egypt.—Suez.
Aden Protectorate.—Aden.
India.—Bassein, Bombay, Rangoon.
Ceylon.—Colombo.
China.—Amoy.

CHOLERA

India.—Bassein, Calcutta, Moulmein.
Siam.—Bangkok.
French Indo-China.—Haiphong, Saigon.

SMALLPOX

Iraq.—Basra.
India.—Bombay, Calcutta, Madras, Moulmein, Negapatam, Rangoon.
French India.—Pondicherry.
Dutch East Indies.—Belawan-Deli.
China.—Shanghai, Hong Kong.
Japan.—Kobe, Shimonoseki.
Kwantung.—Dairen.

Returns for the week ended May 19 were not received from Vizagapatam or Tuticorin, India.

CANADA

Provinces—Communicable diseases—Week ended May 19, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from seven Provinces of Canada for the week ended May 19, 1928, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever				2				2
Influenza	10			8				18
Lethargic encephalitis				1				1
Poliomyelitis							1	1
Smallpox		2		12	1	13	10	38
Typhoid fever		2	16	7				25

Quebec Province—Communicable diseases—Week ended May 26, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended May 26, 1928, as follows:

Disease	Cases	Disease	Cases
Chicken pox	18	Scarlet fever	80
Diphtheria	46	Smallpox	15
German measles	11	Tuberculosis	62
Influenza	7	Typhoid fever	10
Measles	158	Whooping cough	10

DENMARK

Communicable diseases—March, 1928.—During the month of March, 1928, communicable diseases were reported in Denmark as follows:

Disease	Cases	Disease	Cases
Bronchopneumonia	3,362	Paratyphoid fever	5
Cerebrospinal meningitis	8	Pneumonia	691
Chicken pox	62	Poliomyelitis	3
Diphtheria	590	Puerperal fever	21
Erysipelas	257	Scarlet fever	219
Influenza	5,587	Tetanus	1
Jaundice	113	Tuberculosis	272
Lethargic encephalitis	12	Typhoid fever	10
Measles	5,728	Undulant (Malta) fever	[1] 87
Mumps	657	Whooping cough	1,757

[1] Reported from State Serum Institute.

Population: 3,493,000.

PERU

Arequipa—Mortality, March-April, 1928.—Mortality from all causes was reported at Arequipa, Peru, during the months of March and April, 1928, as follows: March, 1928, deaths, 70; April, 1928, deaths, 59. Deaths from certain causes were distributed as follows: Gastroenteritis—March, 17; April, 4; tuberculosis—March, 14; April, 16; typhoid fever—one death each in March and April; typhus fever—one death in April.

SPAIN

Mortality from all causes and from certain diseases—July-September, 1927.—During the three-month period July to September, 1927, inclusive, the total number of deaths occurring in Spain from all causes was as follows: July, 36,596; August, 33,717; September, 29,279. Population, 22,290,162. Deaths from certain diseases were reported as follows:

Deaths, 1927

Disease	July	August	September	Disease	July	August	September
Bronchitis:				Pneumonia	519	484	462
Acute	837	745	722	Puerperal fever	104	114	114

DIVISION OF SANITARY REPORTS AND STATISTICS

ASST. SURG. GEN. R. C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

OCCUPATIONAL MORTALITY AMONG MALES IN ENGLAND AND WALES, 1921-1923

A Summary of the Report of the Registrar General

By ROLLO H. BRITTEN, *Associate Statistician, Office of Industrial Hygiene, United States Public Health Service*

Because of the fact that the recently issued report on occupational mortality among males in England and Wales[1] will not be generally available in this country, a summary of this report has been prepared. It is, of course, not possible to present the material in any detail, and research workers in the field of industrial hygiene will desire to study the original volume, because of its great significance. At the same time, the outstanding features are of sufficient general interest to warrant a discussion of them. No attempt at a thorough analysis or digest has been made, both because the delay would detract from the timeliness of this paper, and because a really adequate study must be made by persons closely familiar with occupational health conditions in England.

Since death rates by occupation for the general population have not been available in the United States in recent years, the English data prove particularly valuable to us in a field in which we have no comparable material. In many particulars, the occupational mortality rates in England are not generally applicable here, but they are exceptionally suggestive. In a way they mean more to us than corresponding rates for the United States could mean, because in England the worker is more likely to remain in a specific occupation throughout his life, and thus his death may be more properly ascribable to the occupation given on the death certificate.

The current English report departs radically from preceding volumes—so much so that it must be accepted forthwith that few comparisons with the previous material are legitimate. The primary cause of this was the adoption by the English Census Bureau of a revised occupational classification in 1921. An attempt is now made to distinguish occupations on purely occupational lines. For instance, cutlery grinders are now given by themselves. An excess mortality from all causes of 230 per cent is found for them, whereas in the previous report they were combined with all others concerned in the manufacture of cutlery, showing an excess of only 63 per cent.

[1] Registrar General's Decennial Supplement, England and Wales, 1921, Part II, Occupational Mortality, Fertility, and Infant Mortality. London: 1927.

In view of the changes in the census classification, no attempt was made in the present registrar general's report to keep the data comparable in other particulars with preceding reports. Among the changes that should be mentioned are the following: The comparative mortality figures are now calculated so as to yield 1,000 deaths at the death rates for different ages, from 20 to 65 years, prevailing among all occupied and retired civilian males in 1921–1923 for the same ages. In 1910–1912 these figures were based on all males; for 1900–1902, ages 25–65. In this paper, as a matter of simplicity, the comparative mortality figures themselves have not been used,[3] except in one or two tables, but it must still be kept in mind that the standardized rates are for ages 20–65 instead of 25–65, and refer to all occupied and retired males, instead of all males. A rearrangement of occupations by social class was made, there being now five such classes (I, upper and middle; II, intermediate between upper and middle and skilled labor; III, skilled labor; IV, intermediate between skilled and unskilled labor; V, unskilled labor). The years 1921–1923 have been used instead of 1920–1922 (which would have been consistent with previous reports). It was felt that industrial conditions were still abnormal in 1920 as a result of gradual demobilization following the war, and, furthermore, the new census classification as to occupation and the 1920 international list of causes of death could not have been used for the year 1920.

It should be noted that in the present volume retired have been included with the occupied, since they were formerly employed in the occupation with which they are grouped. Also the tables are limited to civilians. As a matter of brevity, the term "all occupied" in this paper has frequently been substituted for "all occupied and retired civilian males."

First, a summary of what is contained in the British report is desirable, since only certain phases of it can be covered in this paper. After a discussion of the mortality by social class, the important causes of death are considered, with tables giving the occupations with the highest and lowest comparative mortality figures for each disease. Then the opposite point of view is taken and each important occupation is discussed seriatim. The next section deals with occupational fertility—i. e., the number of births to men in each occupation for the year 1921. These data were previously carried in the general report of the registrar general. A further section discusses infant mortality, treated in the same way. Many of the detailed tables also take up occupational fertility and infant mortality, but only brief reference will be made to this material in the present review. Then follows a series of tables dealing with the various

---

[3] The standardized rates used were obtained by multiplying the "comparative mortality figures" by a factor, the rate for all causes among all occupied and retired males.

phases of the material, including registered and calculated deaths from all causes according to the detailed occupations employed by the census bureau; mortality for all causes in various ages by the abbreviated occupational classification used generally in the volume, expressed as a ratio to all occupied and retired; comparative mortality figures by occupation and causes, both where the rate for all causes is taken as 1,000 and where the rate for each cause is taken as 1,000; various ranking tables according to occupation; mortality at various ages by cause and social class, expressed as a ratio to all occupied and retired; and finally a detailed set of "abstracts" giving the number of deaths and the specific death rates by age, cause, and occupation. One can hardly fail to realize from this brief summary the great value which the report possesses and the more elaborate treatment of the material than in previous reports.

The present paper is divided into six parts, for convenience:

I. Social distribution of mortality.

II. A comparison for all occupied males with 1910–1912.

III. Industrial comparisons for mortality, fertility, and infant mortality.

IV. Specific occupational comparisons according to major causes of death.

V. Summary of standardized rates by occupation.

VI. Mortality by age from a few causes in larger occupations.

In interpreting occupational mortality, one must be forewarned as to possible fallacies. Perhaps this can most readily be done by quotation from the bulletin itself:

It can not be assumed that the deaths tabulated for any occupation have occurred exclusively amongst the men tabulated to that occupation. So far as this is the result of ordinary changes of occupation by men in normal health, as from agricultural laborer to policeman or farm bailiff, the returns are probably not prejudiced, * * * for as such changes of occupation are always going on the census figure may be regarded, at all events in normal times, as representing an unprejudiced and typical sample of the occupational population during the period supplying the deaths, and with which they may therefore be fairly compared, even if they are not individuals actually included in the census occupational population in question * * *.

But a more important source of discrepancy between the census and registration figures collated in the tables is probably to be found, not in economic, but in health considerations. The reader must be reminded, as in previous reports of this series, that the weakly puddler or blacksmith may be forced to adopt a less strenuous occupation before his death. If so the occupation at death (the last occupation before work ceased) may differ from that at census if change of occupation has occurred shortly after the census, and death shortly after the change * * *. But even when the death corresponds with the occupational return at census the same fallacy may apply in only slightly less degree. For the former puddler may be obliged by bronchitis, skin cancer, or other chronic disease incidental to his calling to become a costermonger for years before his death, in which case the deaths correspond with the census return, although

really pertaining by origin to another occupation. The only difference in this case is the transfer of one life from puddlers to costermongers in correspondence with the death, but at most ages this goes a very short way toward compensating for the death transfer. This type of error must evidently tend toward understatement in some degree of the mortality of strenuous occupations, and corresponding overstatement of those open to men of impaired physique, but no measure of the extent of this tendency can be applied * * *.

Besides these general instances there are doubtless many others applying particularly to certain occupations, but under our present system of national records no means of avoiding this difficulty has ever suggested itself * * *.[3]

There are two additional sources of error which require specific mention. For one thing, there is a tendency for the classification of occupations to become yearly more specific so far as the census returns are concerned, and it is probable that the same minuteness does not always apply to the occupation as recorded by the physician on the death certificate. Hence, for certain specific occupations the population may be too great to correspond with the mortality, giving unreasonably low rates. This perhaps explains why the mortality from all causes for farmers' sons and other relatives assisting in the work of the farm is only 22 per cent of that for all occupied (when age has been taken into account), while the rate for farmers is 71. Many other examples could be cited.

A second source of error seems to us to be of very great significance. In a sense it is covered by the comment above as to the transfer of a puddler to the occupation of costermonger by reason of some disease incident to his former occupation. But the effect is too vast to be explained purely on the basis of diseases incident to strenuous occupations. There is in industry a general tendency for the stronger bodied to go into the more strenuous occupations, and for the weaker to seek the less strenuous. The high mortality among costermongers can not be explained, it seems to the writer, on the basis of deaths associated with some prior occupation which these men had. In general it appears to be the result of a selective process of such subtle and sweeping effect that occupational mortality figures must always be judged with this factor in mind. Drivers of horse-drawn vehicles have extraordinarily high mortality rates from nearly every cause. They must have been on the average more or less inferior physically throughout their lives. They may never have been employed in any very active occupation. In many occupations this selective factor seems to have been at work, and when it is combined also with complications due to varying rates by social class or economic conditions, we are faced with difficult problems indeed.

A final caution as to interpreting mortality records in general. All studies of autopsy material indicate that the correct cause of death is

[3] At another point of the bulletin reference is made to the fact that as life advances there is a tendency to omit the occupation on the census return, whereas it would appear on the death certificate. This is very important and tends to increase the mortality rates of the advanced ages, but has not been considered here, because it has been felt safer to omit mortality rates for the advanced ages.

by no means always placed upon the certificate. Understatement of syphilis and some other causes is to be expected from obvious reasons; but the difficulty is of much wider scope, involving many causes of death, and of varying effect in the different social classes and in particular occupations. It is no doubt also responsible for more or less correlation between causes of death, because of a confusion in the record. There is, moreover, the obstacle of deaths due to more than one disease entity. All rates must be scrutinized for errors of this character before conclusions are drawn, and conclusions must always be accepted with reservation.

Since this review of the British mortality was undertaken particularly to be of use to the industrial hygienist in the United States, international difference in certifying causes of death becomes a point which can not be disregarded. The high mortality rates for chronic bronchitis in these tables may surprise a reader who is not familiar with such differences. As a matter of fact, the death rates for chronic bronchitis in this country are usually about one-fourth of those in England and Wales. In regard to this point, Newsholme [4] states:

> The contrast * * * between death rates in England and in the United States shows a great unexplained excess of mortality from bronchitis in England. * * * In the United States the certification of chronic bronchitis is discouraged: Thus in New York medical certificates stating chronic bronchitis as the cause of death are sent back for revision.

It should be added that if the two causes of death are given on the same death certificate, one must be lost sight of in the compiled figures. In the United States this is handled according to a series of rules in the Census Bureau; in England the opinion of the physician is usually followed. This may in part explain the difference in the mortality rates from bronchitis.

With regard to other points of incomparability, it may be stated that in the United States cerebral hemorrhage is favored over arterial disease, while in England it is treated as secondary to and therefore a complication of arterial disease. Quoting further from Newsholme:

> Arteriosclerosis is not provided with a separate column in the American statistics; in England it appears to be superseding cerebral hemorrhage as a cause of death. Renal disease is a common cause of cerebral hemorrhage, and the fact that deaths under this heading are seven times, while deaths under cerebral hemorrhage are only two and one-half times, as many in the United States as in England, points to considerable incomparability in the data.

I. Social Distribution of Mortality

The mortality in different occupations is affected in a marked manner by the social status of the workers, involving, as this does, economic differences and environmental distinctions outside the factory. The registrar general has recognized this fact by classifying the oc-

[4] Elements of Vital Statistics. Sir Arthur Newsholme. 1923.

cupations according to social class. Inaccurate as such a classification necessarily is, considerable interest attaches to the mortality rates in the several social classes, especially in their bearing on the rates in specific occupations. Some effect of occupational hazards, direct and indirect, on the rates for each social class must be allowed for, but the extent of this effect is indeterminate.

First are presented the standardized mortality rates, by social class, for the ages 20–65 according to cause of death. The standardized rate is used in preference to a crude rate, since it affords a convenient average which more or less eliminates differences due to variations in the age distributions of the populations involved. The social classification seems clear without further comment, beyond noting that the allocation into the social class was done by specific occupation, not by individuals.[5] The diseases are arranged in an order based on the tendencies of the rates to vary from class to class, at the top being those in which the rates are highest in social classes IV and V.

TABLE 1.—*Standardized mortality of the five social classes, from all causes and from certain causes, at ages 20 to 65 years, 1921–1923*

Cause	Death rate per 100,000				
	Class I, upper and middle	Class II, intermediate	Class III, skilled labor	Class IV, intermediate	Class V, unskilled labor
Bronchitis	11.6	24.9	42.5	54.3	80.0
Old age	.5	.8	1.4	1.3	3.0
Respiratory tuberculosis	73.2	126.3	146.2	150.2	209.5
Hernia	1.7	2.3	2.8	3.7	4.1
Valvular heart disease	33.0	52.3	55.9	61.6	74.0
Chronic rheumatism, etc	1.9	2.7	3.2	3.0	3.6
Ulcer, stomach	6.7	8.1	9.3	10.1	12.2
Pneumonia	64.5	65.5	69.7	83.4	116.9
Other tuberculosis	9.2	12.4	12.4	12.4	13.5
Syphilis, etc	18.0	22.6	23.9	23.8	34.7
Other respiratory	10.9	13.9	13.5	15.0	18.4
Cancer	93.8	108.1	116.3	113.3	144.4
Influenza	27.8	31.2	31.1	37.4	39.3
Other nervous	23.8	27.8	27.2	28.5	36.9
Accident	36.5	31.6	42.8	58.4	54.2
Acute nephritis	2.7	4.4	4.1	3.6	4.4
Cerebral hemorrhage	36.3	42.3	40.9	38.7	44.4
All causes	743.0	862.0	870.0	921.0	1,151.0
Chronic interstitial pneumonia [1]	1.0	.9	1.6	1.2	1.1
Other genito-urinary	7.5	7.1	6.9	8.1	10.4
Chronic nephritis	31.4	35.6	30.6	28.7	33.6
Other heart	63.8	65.5	54.0	55.3	69.2
Other causes	49.4	44.7	43.9	42.0	44.8
Intestinal obstruction	5.9	5.0	4.0	4.9	5.7
Ulcer, duodenum	6.4	5.9	4.7	5.1	6.0
Suicide	25.7	28.4	20.1	19.8	21.7
Other digestive	20.6	17.5	14.5	14.0	17.1
Alcoholism	1.1	2.7	.5	7	.7
Arteriosclerosis	29.2	20.4	17.5	15.9	21.5
Diseases of prostate	3.7	4.0	3.5	2.7	2.9
Other circulatory	3.6	2.8	2.2	2.6	2.3
Diabetes	13.9	16.2	10.2	8.4	7.4
Diseases of liver	14.3	16.4	5.8	6.5	7.6
Appendicitis	13.8	11.6	7.2	6.9	5.7

[1] Fibroid phthisis, fibrosis of the lungs, silicosis, miners' phthisis, etc.

[5] The social classes VI, VII, and VIII of the previous report have been combined with one or another of the five classes now used.

The table runs the gamut from bronchitis, with a rate of 11.6 in class I and 80 in class V, to appendicitis, where the figures are 13.8 and 5.7, respectively. One must remember that in some cases the distinctions are artificial, due to differences in diagnosis in the various social classes and to other factors. This influence is shown vividly by the rates for "old age," the rate for class V being six times as high as that for class I, due to more precise statement of the cause of death among the better classes at these advanced ages.

As would be necessary, those diseases which one thinks of as being more or less industrial in origin appear at the top of the table, having higher rates in the social classes most acutely affected by the strain and specific hazards of industry.

Taken roughly, the table suggests that deaths from respiratory conditions are strikingly greater in the lower social levels. The greatest difference lies in bronchitis, but respiratory tuberculosis, pneumonia, influenza, and "other" respiratory diseases all are correlated similarly with social class. Of valvular heart disease this is also true, but not of circulatory diseases in general. The marked difference in hernia is rather surprising. Digestive diseases (except ulcer), diabetes, diseases of the liver, etc., are higher among the better classes, the difference apparently being related to "financial capacity for overindulgence in dietic indiscretions," as Doctor Collis states in his review of the registrar general's report.[6]

Summary of the rates in this table by certain groups of diseases ((*a*) all tuberculosis; (*b*) pneumonia and bronchitis; (*c*) circulatory; (*d*) digestive) shows some striking differences according to social class. In class I the highest rate for any of these four is that of the circulatory disease group, with digestive diseases second, while classes III and V have all tuberculosis for their highest rates, with circulatory second for class III and pneumonia-bronchitis second for class V.

The data relating to cancer have received careful and detailed consideration in the registrar general's report. Possibly sufficient reference will be to quote a paragraph from Doctor Collis's review:[7]

> Apart from cancer of the skin with its definite occupational causation, cancer of the lip, tongue, jaw, esophagus, and stomach as far as the pylorus is found, for each site named and in the order stated, to increase in prevalence from class I to class V; but, when the pylorus is passed, cancer is found attacking the remainder of the digestive tract, and indeed other organs as well, quite indiscriminately when distributed according to social class. Why cancer of the upper alimentary tract displays this remarkable social incidence is not at once obvious.

Mortality from alcoholism needs a more thorough study than can be given to it in this summary; but the presence of alcoholism, digestive diseases, and diseases of the liver at the bottom of the table

---

[6] Journal of Industrial Hygiene, May, 1928 (Vol. X, No. 5), p. 140.
[7] Cited previously.

suggests that intemperance is now to a large extent a privilege of the better social classes, who can afford to be intemperate.

These fragmentary comments do not exhaust all of the meaning in this unique table, but other phases must be left to the reader.

It is not possible to devote space to any elaborately drawn picture of the mortality by age in the several social classes. A table of the rates for five of the commonest forms of death showing markedly higher rates among the poorer classes must suffice. These are the causes of death which are of peculiar interest from an occupational standpoint.

TABLE 2.—*Mortality by age for the five social classes, from all causes and from certain causes, 1921–1923*

Cause and social class	Death rate per 100,000, by age group					
	[1] 15–19	20–24	25–34	35–44	45–54	55–64
All causes, all classes	**247**	**352**	**399**	**639**	**1,156**	**2,572**
Class I	142	237	261	484	985	2,247
II	205	307	376	569	1,090	2,469
III	243	347	380	590	1,070	2,508
IV	248	367	420	609	1,173	2,482
V	299	408	498	880	1,507	3,061
Respiratory tuberculosis	**69**	**136**	**133**	**160**	**166**	**150**
Class I	28	50	57	87	86	82
II	62	121	132	137	125	103
III	71	149	129	151	160	156
IV	59	135	132	164	168	147
V	89	158	161	238	256	228
Cancer, all sites	**3**	**6**	**11**	**40**	**166**	**494**
Class I	3	4	10	24	146	386
II	4	6	12	35	150	458
III	3	6	11	40	160	495
IV	3	5	11	40	163	469
V	3	5	13	51	211	596
Bronchitis	**1**	**3**	**6**	**20**	**56**	**191**
Class I	3	------	1	5	17	47
II	[1] 0	2	4	11	31	168
III	1	3	5	16	50	189
IV	1	4	8	26	66	225
V	2	4	10	41	109	313
Pneumonia	**21**	**28**	**40**	**72**	**103**	**170**
Class I	8	16	26	63	93	144
II	16	29	33	62	87	145
III	20	27	37	63	91	153
IV	22	31	45	80	109	174
V	24	41	61	111	154	251
Valvular heart disease	**10**	**16**	**22**	**36**	**72**	**188**
Class I	3	6	7	17	35	135
II	9	14	18	31	63	177
III	11	15	20	34	69	184
IV	9	16	23	40	76	196
V	15	21	32	50	95	217

[1] Less than 0.5.

What is brought out particularly is the fact that the greatest relative difference occurs in middle life when the effect of industrial activity is most felt. For instance, at 35–44 years the cancer death rate for class V is more than twice that for class I, but after 50 years the difference between the two is not marked at all. So with valvular heart diseases, and in lesser degree with bronchitis. The difference

is not so marked in the case of pneumonia. For all causes, the following table brings out this tendency succinctly. First is given the ratio of the death rate in class III to that in class I; then the ratio of that in class V to that in class III.

TABLE 3.—*Ratio of one social class to another by age, all causes*

Class	Age group					
	16-19	20-24	25-34	35-44	45-54	55-64
III to I	171	146	146	122	109	112
V to III	123	118	131	149	141	122

Class I evidently has an exceptionally low rate under 20 years of age, for more or less obvious reasons. Class V shows the greatest differences from class III at 40 years of age, the ratio declining here more slowly than in the comparison between classes III and I.

With this brief comment, the subject of mortality according to social class must be passed over; but its effect on occupational mortality must be kept in mind during the remainder of this paper. The abbreviated occupational groups which form the basis of most of the comparisons frequently involve specific occupations falling into more than one social class, but where possible the factor of social class will be taken into account. The social class will be shown in roman numerals following the name of the occupation. Where any particular group really includes occupations falling into two social classes, the social class with the larger number of persons is shown. Where the group is composed of both skilled and unskilled workers, it is shown in the intermediate class.

II. A Comparison for all Occupied and Retired Males with 1910-1912

The reason why the registrar general has made no particular effort to keep the present report comparable with the preceding has already been discussed. Although certain occupations may be legitimately compared for the two periods, a detailed knowledge of the classification of occupations would be necessary and much caution in interpretation. It has seemed preferable for the present purpose to omit any such comparisons, and to give, as suggestive of the changes which have taken place, simply the rates for the two periods by disease for all occupied and retired males. This comparison is made in Table 4.

TABLE 4.—*Mortality by age among occupied and retired males, 1910–1912, compared with 1921–1923*

	Death rate per 100,000 by age group					
	[2] 15–19	20–24	25–34	35–44	45–54	55–64
All causes:						
1910–1912	220	352	471	794	1,465	3,004
1921–1923	247	352	399	639	1,156	2,572
Respiratory tuberculosis:						
1910–1912	58	132	168	208	230	220
1921–1923	69	136	133	160	166	150
Cancer, all sites:						
1910–1912	3	5	11	43	169	435
1921–1923	3	6	11	40	166	494
Diabetes:						
1910–1912	3	5	6	8	15	44
1921–1923	3	5	6	7	13	32
Alcoholism:						
1910–1912	[1] 0	[1] 0	2	6	8	8
1921–1923			[1] 0	1	2	1
Cerebral hemorrhage:						
1910–1912	1	2	4	17	69	221
1921–1923	1	2	3	11	49	194

[1] Less than 0.5. [2] In 1921–1923, this group is 16–19.

The marked decline in mortality for all causes (which is found except for ages under 25 years) is disclosed in most causes of death. Notable among the exceptions are valvular heart disease and cancer. It is interesting in the latter case that there is no increase found except at the higher ages, where possibly the effect of improved diagnosis would be most felt. Are we to infer that the British data do not lend much strength to the supposition that cancer mortality is actually on the increase?

Respiratory diseases (tuberculosis and pneumonia) show the most signal improvements. This fact is encouraging; but the data for the present time indicate overwhelmingly the importance of such causes of death in the occupational experience of England. Nor is there reason to believe that respiratory diseases are of any less industrial consequence in the United States.

The decline in cirrhosis of the liver, reflecting with considerable precision the drinking proclivities of a nation, at least with regard to spirituous liquors, is of interest. Chronic nephritis shows a decrease which is of the same order of magnitude.

In connection with the use of cirrhosis of the liver as a possible index of alcoholism, the following quotation is taken from the registrar general's report:

This disease was included in the abstracts as the best available index to alcoholism in occupational mortality tabulation. In former reports of this series two such measures were employed, alcoholism returned as such and cirrhosis of the liver. But conditions have changed. Whereas in 1910–1912 the deaths of 1,339 men aged 20–65 were allocated to alcoholism the corresponding number in 1921–1923 was only 315. As 100 deaths a year in a population of 10,000,000 can form only a very imperfect index to the occupational incidence of alcoholism, reliance for this purpose is now placed entirely on cirrhosis of the liver, to which 2,649 deaths within the same limits of age (20–65) were allocated in the three years. It may, of course, be objected that cirrhosis is not necessarily alcoholic in origin, but evidence of its close association with alcoholism in these returns is discussed on page * * * [see next paragraph]. The mortality comparisons for cirrhosis * * * show that its incidence varies largely in accord with the financial means available for overindulgence.

Publicans form part of a remarkable group of four occupations, all concerned with alcohol, which return the four highest * * * [rates for cirrhosis of the liver, the other occupations being brewers, barmen, and cellar men]. The significance of this fact admits of no doubt, and together with the correspondence between cirrhosis mortality and financial resources (vide infra), it constitutes the evidence of close association of cirrhosis with alcoholism * * *.

III. Industrial Comparisons for Mortality, Fertility, and Infant Mortality

For most of the comparisons as to occupation, the registrar general has used a selected group of 164 occupations which do not include quite all of the occupied males in the country. Out of 9,705,000 occupied and retired workers in England and Wales, aged 20–65, 7,933,000 are included in this selected group. Before taking up this latter group, there seems to be some advantage in considering for a moment the whole industrial population within the age limits of 20 and 65 from the point of view of industry rather than from that of occupation. The volume gives such a table, in which the detailed occupations as listed by the British census are classified into 31 industrial groups. For the present purpose, these industrial groups, with certain important subdivisions, have been chosen.

The table deals only with all causes of death and employs the ratio to all occupied and retired males (based on the standardized rate). As the table also gives the corresponding ratio for births and the infant mortality rate (according to industry and occupation of the father), these figures have been included because of their general industrial interest. With respect to the birth ratio, it may be explained that it is exactly comparable with the death ratio used in

the table, and is thus, so to speak, a "comparative fertility figure."[8] The number of workers in each industry is also supplied.

TABLE 5.—*Industrial mortality, legitimate fertility,[a] and infant mortality* [a]

Class and occupation	Ratio to all occupied and retired males: Deaths (1921–1923)	Ratio to all occupied and retired males: Births (1921)	Infant mortality per 1,000 births (1921)	Number of persons (20–65 years)
All males, occupied and retired	100	101	79	9,704,860
Class I	82	85	38	225,618
Class II	94	85	55	1,974,884
Class III	95	97	77	4,218,715
Class IV	101	109	89	1,984,906
Class V	125	128	97	1,300,737
I. Fishermen	91	130	99	24,485
II. Agricultural occupations	68	107	60	876,400
III. Mining and quarrying occupations:				
1. In coal and shale mines	101	25	103	786,242
2. In metalliferous mines and workings	139	132	98	19,287
3. In other mines and quarries	90	109	84	42,116
IV. Workers in treatment of nonmetalliferous mine and quarry products (exclusive of gas works):				
1. Makers of coke and by-products (exclusive of tar distilling)	72	97	124	8,294
2. Makers of other products	78	104	73	14,128
V. Makers of bricks, pottery, and glass:				
1. Makers of bricks, pottery, and earthenware	126	114	99	49,190
2. Makers of glass and glassware	128	121	86	20,23[illegible]
VI. Workers in chemical processes; makers of paints, etc.:				
1. Workers in chemical processes	89	93	93	31,512
2. Makers of paints, oils (not mineral), etc	90	106	91	20,638
VII. Metal workers (not electroplate or precious metals)	96	98	79	1,229,392
VIII. Workers in precious metals and electroplate	99	91	72	23,482
IX. Electrical apparatus makers and fitters (not elsewhere enumerated), and electricians	85	89	66	112,758
X. Makers of watches, clocks, and scientific instruments	91	74	64	19,261
XI. Workers in skins and leather, and makers of leather and leather substitute goods (not boots or shoes):				
1. Furriers, skinners, tanners, and leather dressers	106	103	78	24,285
2. Makers of leather and leather substitute goods	92	85	62	21,686
XII. Textile workers	105	80	86	274,188
XIII. Makers of textile goods and articles of dress	108	90	70	235,267
XIV. Makers of foods, drinks, and tobacco products:				
1. Makers of foods	88	90	70	120,119
2. Makers of drinks	126	107	81	36,091
3. Makers of tobacco products, cigars, cigarettes, snuff	114	88	65	5,698
XV. Workers in wood and furniture	88	91	70	395,598
XVI. Makers of and workers in paper; printers, bookbinders, photographers, etc	94	84	62	136,926
XVII. Builders, bricklayers, stone and slate workers; contractors	99	119	83	442,446
XVIII. Painters and decorators (not pottery)	111	100	75	177,842
XIX. Workers in other materials:				
1. Workers in rubber, vulcanite, ebonite	91	96	64	15,054
2. Workers in bone, horn, ivory, celluloid, etc	112	81	71	2,420
3. Workers in other materials	109	87	59	9,364
XX. Workers in mixed or undefined materials (not elsewhere enumerated)	94	104	89	80,087
XXI. Persons employed in gas, water, and electricity undertakings (not elsewhere enumerated)	97	108	85	44,564
XXII. Persons employed in transport and communication:				
1. Railway workers	83	94	76	275,258
2. Road transport workers	110	107	83	459,415
3. Water transport workers	158	143	97	247,623
4. Other workers in transport and communication	110	96	75	157,752
XXIII. Commercial, finance, and insurance occupations (exclusive of clerks):				
1. Commercial occupations	103	85	64	813,898
2. Persons employed in finance and insurance	90	73	48	91,920
XXIV. Persons employed in public administration and defense (excluding professional men and typists):				
1. Public-administration	80	81	55	236,801

[a] According to occupational classification of infant's father.

[8] Ratio to the number of births which would have occurred if the fertility rates at the various age groups in the several occupations had borne the same relations to each other as those stated for all married males in the 1921 census, the rates being increased to yield the number of births registered in 1921.

TABLE 5.—*Industrial mortality, legitimate fertility, and infant mortality*—Contd.

Class and occupation	Ratio to all occupied and retired males		Infant mortality per 1,000 births (1921)	Number of persons (20-65 years)
	Deaths (1921-1923)	Births (1921)		
XXV. Professional occupations (excluding clerical staff)	83	80	41	276,164
XXVI. Persons employed in entertainments and sport	121	82	73	57,568
XXVII. Persons engaged in personal service (including institutions, clubs, hotels, etc.)	121	70	80	285,326
XXVIII. Clerks and draftsmen (not civil service or local authority); typists	99	75	51	447,367
XXIX. Warehousemen, storekeepers and packers	97	88	74	179,986
XXX. Stationary engine drivers, dynamo and motor attendants	86	102	90	139,911
XXXI. Other and undefined workers	132	122	91	736,668

This summary will serve chiefly as a background for further tables. One can not single out from it occupations with special hazard to health, but he can get a clear idea as to the fluctuations in industry around the rate for all occupied males. Industries with relatively low rates will not appear in subsequent tables. It is interesting to note that agricultural occupations have a mortality which is 32 per cent below the average. No discussion of the data for fertility and infant mortality by occupation of the father will be undertaken in this survey, but it is of moment to recognize that we find the same correlation with social status in the birth and infant mortality rates (based on the occupation of the father) as was found previously in the case of the death rate from all causes.

IV. Specific Occupational Comparisons According to Major Causes of Death

In studying mortality in relatively small occupational groups, a single summary figure is a prerequisite. What we are looking for are clues to hidden industrial hazards; and at the present stage of knowledge of industrial hygiene and its application, these must be looked for mostly in small groups of workers. The hazards of larger groups have been rather well understood for a long time, because interest of the general public has centered upon them. To obtain a satisfactory age curve for any disease, it appears that approximately 50,000 persons are required in the group—much larger than any group that is likely to contain hidden industrial hazards. Accordingly, this paper will place chief emphasis on the standardized rate—i. e., on an average figure for each occupation which makes allowance for differences in age distribution. These data will be supplemented by such age curves as are suggestive. A study of occupational mortality by age, however, is not so much a research into the hazards of specific occupations as it is into the manner in which industrial life in general reflects itself in the different causes of death.

To industrial hygienists in this country, the tables presented here are very suggestive, because they give actual rates—i. e., the number of deaths in a known population. American occupational mortality

statistics have never successfully been calculated on such a basis. Furthermore, the effect of age has been eliminated by determining what the rates would be if applied to a single age distribution for all of the occupations. This correction is of extreme importance in dealing with this subject, since the groups frequently differ widely as to age.

At the risk of burdening this paper with an excess number of tables, it has been felt almost necessary to give the occupational mortality by disease in successive tables, with a summary at the end in which the rates for different diseases in one occupation can be brought together. (Sec. V.) This method makes it possible to arrange the occupations in the order of the rates, singling out for special attention those which have very excessive rates.

However, it was important not to confuse the reader by including in the tables rates which are not particularly high or which were based on too small numbers to be statistically significant. Accordingly, the only rates included in this series of tables are those which are significantly above the rates for all occupied and retired males. The criterion used was the probable error,[9] and no rates appear where the difference between the rate and that for all occupied and retired males is less than three times the probable error. It was not necessary to calculate the probable error of the difference itself, since the rate for all occupied and retired males is based on a very large population and has no appreciable error from the point of view of simple sampling.

In using such a criterion no inference is possible that these occupations have significantly high rates as a result of the occupation per se. As explained previously, social and environmental conditions not associated with the industry and the question of selection of workers enter into the magnitude of the rates. However, the method does eliminate any occupation having a high rate due purely to small numbers. That this elimination is of considerable importance will be evident to anyone who has dealt with official vital statistics.

An exception to the rule was made in the case of occupations in social class V. So frequently were the rates for this class well above those for all occupied that it seemed well to include only class V occupations where the rates were significantly above those for that class (using three times the probable error as before) instead of above those for all occupied and retired males. None of the diseases specifically considered in this series of tables have lower rates in class V than in the other classes.

---

[9] When added to and subtracted from an average or rate, the probable error fixes the limits within which it is an even chance that the true average or rate would be found. In the case of an average it is obtained by multiplying the standard deviation by 0.6745 over the square root of the number of items. In the case of death rates, it is obtained similarly, using the formula for the standard deviation given from simple sampling—i. e., the square root of the product of p and q divided by n, where p is the chance that the death will occur (or the death rate per person), q the difference between this figure and unity, and n the population. Adjustment has been made for the fact that the data cover three years and are therefore more stable than data for a single year.

TUBERCULOSIS

It is fitting that the first disease to be considered is respiratory tuberculosis, which is the industrial disease of greatest importance at the present time in spite of its rapid decrease in the general population. The table follows.[19] It gives also the rank of the occupations, as do the succeeding tables.

TABLE [illegible].—*Standardized mortality from respiratory tuberculosis in occupations with rates above average, males aged 20–65, 1921–1923, in England and Wales*

Occupation group No.	Occupation	Mortality rate (standardized)
13a	Tin and copper mine, underground workers, not superintending staff (III)	1,886.0
13	Tin and copper miners, not superintending staff (III)	1,323.5
40a	Grinders in the cutlery trade (IV)	1,178.5
40	Metal grinders (IV)	636.7
95	Slate masons and slate workers (III)	512.5
18	Potters' mill workers; slip makers; potters (III)	411.4
153	Barmen (IV)	402.5
38	File cutters (III)	365.3
101	Drafters and brush makers (III)	355.5
127	Costermongers, hawkers, and street sellers (V)	342.4
37	Cutlers (III)	336.0
20	Earthenware, china, etc., kiln and oven men (III)	335.6
118	Stevedores (IV)	333.9
41	Metal glazers, polishers, buffers, and moppers (IV)	317.8
30	Brass foundry furnacemen and laborers (IV)	317.6
35	Brass finishers and turners (III)	308.2
160a	Warehousemen, textiles and clothing (III)	306.3
94	Masons, stone cutters and dressers (III)	304.0
76	Tobacco factory operatives (III)	299.6
120	Other dock laborers [a] (V)	284.7
66	Cutters of textile goods and clothing (not machine cutters) (III)	280.9
71	Skilled boot and shoe operatives, not clickers or cutters (III)	272.4
70	Boot and shoe clickers and cutters (III)	272.2
24	Other skilled glassworkers [b] (III)	270.0
122	Porters (V)	269.2
36	Coppersmiths (III)	266.1
68	Hat formers, plankers and stiffeners (III)	259.5
164	General undefined laborers (V)	246.8
80	French polishers (wood polishers) (III)	245.5
154	Waiters (III)	242.2
157	Chimney sweeps (III)	240.4
15	Slate miners and quarriers (IV)	238.4
54	Wool and worsted card, comb or frame (not spinning frame) tenters (IV)	238.0
75	Cellarmen (IV)	236.0
130	Insurance agents and canvassers (III)	234.7
148	Actors (III)	229.4
48	Skilled lime and tanyard workers, curriers, and leather dressers (III)	225.4
156	Hairdressers, etc. (III)	217.0
23	Skilled glasshouse workers (III)	215.3
67	Tailors, tailors' pressers and machinists (III)	212.5
115	Omnibus and tram conductors (IV)	212.3
149	Musicians (III)	207.1
152	Inn, hotel keepers, publicans (II)	201.1
162	Packers (IV)	198.9
112	Drivers of horse-drawn vehicles (IV)	197.0
69	Boot and shoe makers and repairers (not factory workers) (III)	195.5
124b	Salesmen, etc., in businesses for the sale of grocery and provisions (III)	193.1
124c	Salesmen, etc., in businesses for the sale of textiles and clothing (III)	193.1
84	Hand compositors (III)	192.9
87	Printing machine minders and assistants; machine rulers (III)	186.6
44	Tinsmiths and sheet-metal workers (III)	186.6
158	Clerks (not civil service or local authority); typists (II)	185.6
160	Warehousemen (III)	172.9
110	Railway porters and lampmen (IV)	172.1
32	Machine tool workers and metal spinners (IV)	165.4
124	Salesmen and shop assistants (III)	162.9
	All occupied and retired males	149.6

[a] Exclusive of stevedores, and coal-boat loaders and dischargers.
[b] Exclusive of skilled glasshouse workers, and glass blowers and finishers (not machine hands).

[19] The standardized rates in this table and the succeeding tables will not be found in the registrar general's report. They were obtained by multiplying the comparative mortality figures by a factor—the rate for all causes among all occupied and retired males.

In the present occupational classification of the English census, it has been possible to distinguish between underground and other tin and copper miners, and between grinders in the cutlery trade and others in the group previously termed "cutlery, scissors grinder." As a result we find the sensationally high rates, respectively, of 1,886 and 1,178 per 100,000 population, while the "all occupied and retired" rate is 150. These occupations show the result of a specific hazard—silica dust—as do several others in this list. In fact, the table suggests that dust is the one industrial hazard of a specific nature causing high rates from respiratory tuberculosis. However, there are general or indirect causes affecting the rates in many occupations. Impossible as it is to separate out the factors responsible in occupations such as barmen, costermongers, stevedores, porters, etc., it is clear that there are excessive rates in many occupations and that an important problem for the industrial hygienist is the isolating of the factors responsible. With regard to this point, the British report states that "the mortalities for separate occupations are very largely governed by their social circumstances."

If the general living conditions are the cause of the high rates in some particular occupations, there might be expected to be noted also a high death rate from all causes. Some meaning thus attaches to the relation between the rate for tuberculosis and that for all causes for a particular occupation. A supplementary table has been prepared to give the ratio of the standardized respiratory tuberculosis rate to that for all other causes. The rate for respiratory tuberculosis was first deducted from that for all causes to make the ratio more sensitive. These ratios must not be confused with proportionate mortality. They have been based on rates adjusted for differences in age in the various occupations. Such differences are a very serious obstacle in proportionate mortality figures for a disease like tuberculosis, because the difference is likely to produce one effect on the tuberculosis death rate and the opposite on the "all-cause" rate. Occupational groups with a large proportion of young persons will have a high percentage of deaths from tuberculosis and a low percentage from all causes; the reverse will be true of occupations with a large proportion of old persons. This error is largely corrected in the present comparison, where the ratio is based on standardized rates. The table has been carried down only to ratios of 25, to save space and concentrate attention on the occupations having real hazards. Occupations with ratios below this limit are quite likely to reflect living or social conditions rather than industrial hazards.

TABLE 7.—*Ratio of standardized respiratory tuberculosis rate to that for all other causes,[1] by occupations*

Occupation group No.	Occupation	Ratio	Rank in previous table	Rank here
18a	Tin and copper mine, underground workers (III)	90.6	1	1
13	Tin and copper miners, not superintending staff (III)	79.4	2	2
40a	Grinders in the cutlery trade (IV)	64.2	3	3
40	Metal grinders (IV)	54.3	4	4
95	Slate masons and slate workers (III)	54.1	5	5
101	Drafters and brush makers (III)	41.7	9	6
37	Cutlers (III)	40.2	11	7
76	Tobacco factory (III)	39.8	19	8
15	Slate miners and quarriers (IV)	38.1	32	9
18	Potters' mill workers; slip makers; potters (III)	37.7	6	10
70	Boot and shoe clickers and cutters (III)	36.9	23	11
36	Coppersmiths (III)	36.5	26	12
71	Skilled boot and shoe operatives (III)	36.2	22	13
66	Cutters of textile goods and clothing (III)	35.7	21	14
35	Brass finishers and turners (III)	35.2	16	15
130	Insurance agents and canvassers (III)	32.8	35	16
41	Metal glazers and polishers (IV)	31.7	14	17
94	Masons, stone cutters, and dressers (III)	31.5	18	18
160a	Warehousemen, textiles and clothing (III)	30.8	17	19
115	Omnibus and tram conductors (IV)	30.6	41	20
157	Chimney sweeps (III)	30.5	31	21
67	Tailors, tailors' pressers, and machinists (III)	29.7	40	22
30	Brass foundry furnacemen and laborers (IV)	29.4	15	23
124b	Salesmen—sale of groceries and provisions (III)	29.3	47	24
118	Stevedores (IV)	29.2	13	25
127	Costermongers, hawkers, and street sellers (V)	29.1	10	26
153	Barmen (IV)	29.1	7	27
48	Skilled lime and tanyard workers, curriers, etc. (III)	28.5	37	28
80	French polishers (III)	27.9	29	29
38	File cutters (III)	27.5	8	30
84	Hand compositors (III)	26.5	49	31
24	Other skilled glassworkers (III)	26.3	24	32
120	Other dock laborers (V)	25.5	20	33
68	Hat formers, plankers, stiffeners (III)	25.5	27	34
87	Printing-machine minders and assistants (III)	25.4	50	35
44	Tinsmiths and sheet-metal workers (III)	25.3	51	36
20	Earthenware, china, etc., kiln and oven men (III)	25.1	12	37
	All occupied and retired males	19.5		
	Social class V	22.2		

[1] All other causes equals 100.

The significance of dust as a cause of occupational tuberculosis is stressed in this table. Of the first 20 occupations in the list, not more than 2 or 3 can be regarded as nondusty. Quite evidently the dust is primarily silica. Many dusty occupations which previously ranked some distance down the list have now taken a position near the top, such as tobacco-factory employees (rank 19 to rank 8), slate miners, and quarriers (32 to 9), boot and shoe clickers, and cutters (23 to 11). On the other hand, occupations where the hazard is nonspecific or where conditions outside the factory are responsible have been moved down, such as barmen (rank 7 to rank 27), costermongers (10 to 26), stevedores (13 to 25), other dock laborers (20 to 33). These are groups in which alcoholism may be thought to play an important rôle.

It is still apparent that there is an excess of tuberculosis in certain occupations where some other specific hazard besides dust may exist—e. g., in tailors and cutters of textile goods, boot and shoe clickers

and skilled boot and shoe operatives, hand compositors and machine compositors, printing-machine minders, and bookbinders.

CHRONIC INTERSTITIAL PNEUMONIA

This cause of death is used as a generic title for such forms of disease as fibroid phthisis, fibrosis of the lungs, silicosis, miners' phthisis, etc., when returned as nontuberculous. Thus it may be most appropriately discussed at this point rather than under acute pneumonia. The disease is purely occupational in nature (where correctly returned), and only 398 deaths were so classified in all occupations in the three years. The table follows:

TABLE 8.—*Standardized mortality from chronic interstitial pneumonia in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
13a	Tin and copper mine—underground workers, not superintending staff (III)	499.9
13	Tin and copper miners, not superintending staff (III)	330.3
40a	Grinders in the cutlery trade (IV)	60.6
94b	Masons, sandstone (III)	56.1
14c	Stone miners, quarriers and sandstone (IV)	34.1
40	Metal grinders (IV)	30.7
94a	Masons, limestone (III)	28.0
94	Masons, stonecutters and dressers (III)	26.7
12	Iron-ore mine, underground workers, not superintending staff (III)	16.4
18	Potters' mill workers; slip makers; potters (III)	*15.7
21	Brick, tile, etc., kiln and oven men (III)	*14.3
14	Stone miners and quarriers (IV)	10.6
9	Coal mine, persons making and repairing roads (IV)	5.4
22	Other persons engaged in the manufacture of bricks, tiles, and pottery (V)	*4.0
14b	Stone miners, quarriers and limestone (IV)	3.7
7	Coal mine, hewers and getters (III)	3.1
	All occupied and retired males	1.2

* Difference less than 3 times the probable error.

The starred rates are included, although not three times the probable error. They are still suggestive of a hazard, since we are dealing with a cause of death which presumably does not occur except where a hazard exists. It should be stated, though, that not more than four deaths occurred in any one of these occupations.

In regard to these figures, the British report makes a comment which should be included here:

The enormous preponderance of Cornish miners' mortality in this list may not altogether represent the facts, for it is very natural that in a case like this, where many instances of a disease rare elsewhere are met within a limited area, it should there be more completely distinguished in certification from other similar forms of disease. Nearly all of the mortality represented in the above list, it will be noticed, is associated in one way or another with stone, whether this is worked in mining for tin and copper, coal, iron ore, or in stone mining and quarrying and dressing. The potters' risk may be attributed to the flint dust used, and the metal grinders' to the dust from grindstones, but it is difficult to conceive of any special occupational risk accounting for the four deaths of artists. It

will be noticed that the risk for coal miners is highest in the case of the makers and repairers of road, who drive shafts and passages through the rock, giving access for the hewers to the working places where the coal itself is cut.

The reader will not fail to notice the contrast between the rates among workers in sandstone compared with those among workers in limestone.

Owing to the large numbers involved, it is of importance to note especially the rates for coal miners. (Occupational groups 7 and 9.)

BRONCHITIS

The table for bronchitis follows:

TABLE 9.—*Standardized mortality from bronchitis in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
40a	Grinders in the cutlery trade (IV)	330. 5
55	Cotton strippers and grinders and card-room jobbers (IV)	253. 2
18	Potters' mill workers; slip makers; potters (III)	246. 7
13a	Tin and copper mine, undergound workers, not superintending staff (III)	227. 1
20	Earthenware, china, etc., kiln and oven men (III)	222. 1
13	Tin and copper miners, not superintending staff (III)	176. 4
23a	Glass blowers and finishers, not machine hands (III)	146. 0
40	Metal grinders (IV)	143. 2
51	Cotton blow room operatives, skilled (IV)	137. 1
127	Costermongers, hawkers, and street sellers (V)	122. 1
27a	Puddlers (III)	121. 9
23	Skilled glasshouse workers (III)	120 3
22	Other persons engaged in the manufacture of bricks, tiles, and pottery (V)	120. 0
101	Drafters and brush makers (III)	115. 1
120	Other dock laborers (V)	113. 7
24	Other skilled glassworkers (III)	113. 4
122	Porters (V)	98. 7
104	Gas stokers (IV)	96. 2
112	Drivers of horse-drawn vehicles (IV)	92. 8
64	Dye mixers and dyers (IV)	90. 9
153	Barmen (IV)	90. 6
94	Masons, stone cutters, and dressers (III)	90. 5
41	Metal glazers, polishers, buffers, and moppers (IV)	89. 0
58	Cotton doublers, winders, warpers, beamers, etc. (III)	88. 9
164	General and undefined laborers (V)	88. 3
29	Iron foundry furnacemen and laborers (IV)	82. 6
11	Coal mine—workers above ground, not superintending staff (IV)	81. 0
35	Brass finishers and turners (III)	80. 3
124a	Salesmen, etc., in businesses for sale of fish, meat, green grocery, milk (III)	79. 0
28	Metal molders (III)	78. 2
10	Coal mine, other workers below ground (IV)	75. 6
60	Cotton weavers (III)	74. 9
43	Riveters and their laborers (III)	72. 5
8	Coal mine, persons conveying material to the shaft (IV)	70. 4
56	Cotton spinners and piecers (III)	65. 0
7	Coal mine, hewers and getters (III)	64. 7
9	Coal mine, persons making and repairing roads (IV)	64. 4
162	Packers (IV)	63. 5
110	Railway porters and lampmen (IV)	60. 8
27	Persons engaged in smelting, rolling, converting of iron and steel (IV)	58. 5
	All occupied and retired males	45. 4

Like respiratory tuberculosis, bronchitis varies closely with social class, the standardized rate in class V being seven times that in class I, and there are no doubt several occupations in this table which have an excessive rate because of the living and economic conditions of the group; but it is striking that the highest rates appear among skilled workers and reflect, as in the case of tuberculosis, specific

hazards like dust. The high rate among cotton workers suggests that other dusts besides silica are important here, while they did not seem important as predisposing to tuberculosis.

It is to the point to contrast the bronchitis mortality of cotton workers with that of woolen workers in similar jobs, the standardized rates being as follows:

	Cotton	Wool
Carders	74.8	98.8
Spinners	65.0	23.3
Doublers	88.9	35.9
Weavers	74.9	38.3
All occupied	45.4	

If dust is to be regarded as more or less responsible for the high mortality among carders, in both wool and cotton, it is suggested that high temperature (with accompanying high humidity) is a major factor. As the British report states, "Of the three occupations involving high working temperatures in the cotton industry the spinners suffer a bronchitis mortality nearly three times as high in cotton as in wool, doublers about two and a half times, and weavers nearly twice as high."

PNEUMONIA

A table for pneumonia is next given:

TABLE 10.—*Standardized mortality from pneumonia in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
30	Brass foundry furnacemen and laborers (IV)	194.1
40a	Grinders in the cutlery trade (IV)	180.9
118	Stevedores (IV)	180.5
51	Cotton blow room operatives, skilled (IV)	177.4
29	Iron foundry furnacemen and laborers (IV)	176.8
53	Cotton card and frame (not spinning frame) tenters (IV)	169.8
27a	Puddlers (III)	158.7
120	Other dock laborers (V)	156.1
127	Costermongers, hawkers, and street sellers (V)	154.1
153	Barmen (IV)	149.0
40	Metal grinders (IV)	146.8
122	Porters (V)	139.3
24	Other skilled glass workers (III)	134.1
28	Metal molders (III)	133.1
164	General and undefined laborers (V)	131.2
152	Inn, hotel keepers, publicans (II)	125.4
112	Drivers of horse-drawn vehicles (IV)	124.3
104	Gas stokers (IV)	123.5
35	Brass finishers and turners (III)	120.1
27	Persons engaged in smelting, rolling, converting of iron and steel (IV)	117.8
154	Waiters (III)	116.1
139	Registered medical practitioners (I)	113.4
43	Riveters and their laborers (III)	105.3
10	Coal mine, other workers below ground (IV)	104.7
44	Tinsmiths and sheet metal workers (III)	103.8
116	Grooms and horse keepers (IV)	101.4
124a	Salesmen, etc., in businesses for sale of fish, meat, green grocery, milk (III)	96.0
162	Packers (IV)	95.9
123a	Proprietors, etc., of businesses for sale of fish, meat, green grocery, milk (II)	95.1
11	Coal mine—workers above ground, not superintending staff (IV)	94.6
	All occupied and retired males	77.9

Among the occupations with high mortality from pneumonia are several in which the workers are exposed to trying alternations of temperature, such as puddlers and iron and brass foundry workers, and cotton workers. Of not less importance is the group of occupations exposed to dust of one sort or another, such as metal polishers, cutlery grinders, including several occupations in which both dust and high temperature appear to be factors. Rates are also high among the group exposed to adverse weather conditions—dock laborers, drivers of horse-drawn vehicles, riveters, stevedores, etc.

It is important to note that tin and copper miners do not have an excess mortality from acute pneumonia.

TOTAL RESPIRATORY DISEASE (EXCLUSIVE OF TUBERCULOSIS AND INFLUENZA)

There is a certain confusion between mortality from bronchitis and pneumonia. In some cases deaths returned as pneumonia in the higher social classes would be returned as bronchitis in the lower. Therefore, it is desirable to consider also the total respiratory group. Following the custom of the International List, this group is exclusive of influenza and tuberculosis. The former could not affect the total appreciably, and in view of the specific relation of tuberculosis to silica dust exposure, it seems well not to confuse the general respiratory mortality with the inclusion of that cause.

TABLE 11.—*Standardized mortality from diseases of the respiratory system in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
13a	Tin and copper mine, underground workers, not superintending staff (III)	878.4
40a	Grinders in the cutlery trade (IV)	640.0
13	Tin and copper miners, not superintending staff (III)	603.5
20	Earthenware, china, etc., kiln and oven men (III)	407.4
55	Cotton strippers and grinders and card-room jobbers (IV)	398.4
18	Potters' mill workers, slip makers; potters (III)	396.4
40	Metal grinders (IV)	341.1
51	Cotton blow-room operatives, skilled (IV)	337.5
118	Stevedores (IV)	324.3
127	Costermongers, hawkers, and street sellers (V)	308.4
120	Other dock laborers (V)	294.6
30	Brass foundry furnace men and laborers (IV)	292.9
27a	Puddlers (III)	292.0
53	Cotton card and frame (not spinning frame) tenters (IV)	287.5
103	Shipyard laborers, etc. (V)	277.8
24	Other skilled glass workers (III)	274.2
29	Iron foundry furnace men and laborers (IV)	272.9
158	Barmen (IV)	264.2
41	Metal glazers, polishers, buffers, and moppers (IV)	261.5
122	Porters (V)	256.6
23a	Glass blowers and finishers, not machine hands (III)	254.8
164	General and undefined laborers (V)	241.8
112	Drivers of horse-drawn vehicles (IV)	240.4
101	Drafters and brush makers (III)	230.3
28	Metal molders (III)	231.1
104	Gas stokers (IV)	228.2
94	Masons, stone cutters, and dressers (III)	226.5
54	Wool and worsted card, comb or frame (not spinning frame) tenters (IV)	224.1
23	Skilled glasshouse workers (III)	221.2

TABLE 11.—*Standardized mortality from diseases of the respiratory system in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*—Continued

Occupation group No.	Occupation	Mortality rate
58	Cotton doublers, winders, warpers, beamers, etc. (III)	218.1
35	Brass finishers and turners (III)	217.8
64	Dye mixers and dyers (IV)	214.8
10	Coal mine, other workers below ground (IV)	201.9
27	Persons engaged in smelting, rolling, converting of iron and steel (IV)	200.6
11	Coal mine, workers above ground, not superintending staff (IV)	119.5
124a	Salesmen, etc., in businesses for sale of fish, meat, green groceries, milk (III)	188.8
152	Inn, hotel keepers, publicans (II)	187.1
80	French polishers (III)	185.5
43	Riveters and their laborers (III)	184.0
9	Coal mine, persons making and repairing roads (IV)	182.8
56	Cotton spinners and piecers (III)	176.7
117	Bargemen and boatmen (IV)	175.8
8	Coal mine, persons conveying material to the shaft (IV)	173.8
162	Packers (IV)	172.9
116	Grooms and horse keepers (IV)	168.6
7	Coal mine hewers and getters (III)	159.1
123a	Proprietors, etc., of businesses for sale of fish, meat, green groceries, milk (II)	157.3
	All occupied and retired males	138.8

Occupations with high rates may be divided into five groups:

(*a*) Dusty trades—tin and copper miners, grinders in cutlery trades, kiln and oven men, cotton strippers and grinders and card-room jobbers, potters, etc.

(*b*) Trades exposed to high temperatures (with or without high humidity)—brass foundry furnace men, puddlers, cotton workers, etc.

(*c*) Trades with general exposure to bad weather conditions—shipyard laborers, stevedores, other dock laborers, costermongers, drivers of horse-drawn vehicles, etc.

(*d*) Trades which have a tendency to collect groups of inferior physical types—costermongers, drivers of horse-drawn vehicles, etc.

(*e*) Trades in which there is an excessive amount of drinking—barmen, porters, etc.

The significance of respiratory conditions aside from tuberculosis in their relation to industrial health will promptly be recognized.

Under bronchitis was given a comparison as to cotton and wool workers. Similar figures are desirable for respiratory diseases as a whole, and are as follows:

	Cotton	Wool
Carders	287.5	224.1
Spinners	176.7	109.4
Doublers	218.1	109.0
Weavers	149.2	93.3
All occupied	138.8	

In regard to these rates, let us quote the following from the registrar general's report:

The spinning, doubling, and weaving of cotton are carried on at high temperatures (70° to 80°) in order to soften the waxy content of the fiber, and so render it more easily worked while carding-room processes do not involve this requirement. The carders' mortality does not differ greatly in the two industries, being higher from bronchitis for wool and from pneumonia for cotton. Thus it appears that for three textile occupations involving for cotton (but not for wool) workers exposure to artificial heat and moisture, respiratory disease mortality is above average for the cotton workers so exposed and well below it for the woolen workers not subject to these conditions, whereas for carders, who are exposed to much dust but little heat, there is excess in both industries.

INFLUENZA

There is added a table for influenza, although this disease is of minor importance from an occupational point of view.

TABLE 12.—*Standardized mortality from influenza in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
12	Iron ore mine, underground workers, not superintending staff (III)	69.4
64	Dye mixers and dyers (IV)	59.7
29	Iron foundry furnacemen and laborers (IV)	59.6
10	Coal mine, other workers below ground (IV)	58.6
11	Coal mine, workers above ground, not superintending staff (IV)	57.2
117	Bargemen and boatmen (IV)	55.9
9	Coal mine, persons making and repairing roads (IV)	55.6
152	Inn, hotel keepers, publicans (II)	51.5
28	Metal molders (III)	47.0
27	Persons engaged in smelting, rolling, converting of iron and steel (IV)	44.8
164	General and undefined laborers (V)	44.5
8	Coal mine, persons conveying material to the shaft (IV)	44.5
112	Drivers of horse-drawn vehicles (IV)	42.4
7	Coal mine, hewers and getters (III)	36.7
	All occupied and retired males	33.3

Only one occupation (iron ore miners, underground) reveals a death rate twice that of all occupied males. It is perhaps of moment that all of the coal mine groups show an excess. In fact, of the 14 occupations in the list 5 are coal. It should also be observed that iron foundry furnacemen and laborers, metal molders, and persons engaged in smelting, rolling, and converting of iron and steel have rates significantly above those for all occupied.

DISEASES OF HEART

A table for valvular heart disease and one for "other" (chiefly myocardial) heart disease are next given.

TABLE 13.—*Standardized mortality from valvular disease of the heart in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
55	Cotton strippers and grinders and card-room jobbers (IV)	119.7
153	Barmen (IV)	117.4
11	Coal mine, workers above ground, not superintending staff (IV)	95.0
164	General and undefined laborers (V)	86.9
56	Cotton spinners and piecers (III)	86.6
64	Dye mixers and dyers (IV)	84.9
124a	Salesmen, etc., in businesses for sale of fish, meat, green grocery, milk (III)	84.8
60	Cotton weavers (III)	82.0
112	Drivers of horse-drawn vehicles (IV)	78.6
152	Inn, hotel keepers, publicans (II)	77.2
8	Coal mine, persons conveying material to the shaft (IV)	74.5
163	Stationary engine and crane drivers (III)	73.2
123a	Proprietors, etc., of businesses for sale of fish, meat, green grocery, milk (II)	71.9
10	Coal mine, other workers below ground (IV)	71.7
160	Warehousemen (III)	70.5
98	Painters and decorators (III)	65.6
	All occupied and retired males	58.0

TABLE 14.—*Standardized mortality from other heart disease in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
13a	Tin and copper mine, underground workers, not superintending staff (III)	194.7
40a	Grinders in the cutlery trade (IV)	170.1
137	Barristers (I)	150.9
68	Hat formers, plankers, stiffeners (III)	139.1
20	Earthenware, china, etc., kiln and oven men (III)	127.4
75	Cellarmen (IV)	121.8
152	Inn, hotel keepers, publicans (II)	108.8
153	Barmen (IV)	107.6
40	Metal grinders (IV)	107.3
41	Metal glazers, polishers, buffers, and moppers (IV)	103.6
127	Costermongers, hawkers, and street sellers (V)	99.6
122	Porters (V)	99.4
123a	Proprietors, etc., of businesses for sale of fish, meat, green grocery, milk (II)	98.4
124a	Salesmen, etc., in businesses for sale of fish, meat, green grocery, milk (III)	96.3
156	Hairdressers, etc (III)	80.4
112	Drivers of horse-drawn vehicles (IV)	79.3
123	Proprietors and managers of wholesale or retail dealing businesses (II)	78.8
123b	Proprietors, etc., of businesses for the sale of groceries and provisions (II)	76.9
164	General and undefined laborers (V)	76.5
67	Tailors, tailors' pressers, and machinists (III)	75.4
125	Commercial travelers (II)	74.3
	All occupied and retired males	60.0

In the case of valvular heart disease, two quite unlike occupations stand at the top (cotton strippers, etc., and barmen). Although this cause of disease apparently does not reflect occupational differences to the same extent as "other" heart diseases, it should be noted that cotton spinners and weavers (as well as strippers) have rates very much above those for all occupied. Another group with high rates is that of coal miner, an extremely strenuous occupation.

For myocardial disease the order of the occupations with the highest rates is quite different. In fact, very little association between these two causes of death can be found. Quite a number of occupa-

tions have extraordinarily high rates for "other" heart disease, the most interesting feature being the great variations in the nature of the occupations from tin miner to barrister to barmen.

There is a suggestion of an association between myocardial disease and silica risk, in regard to which the registrar general states:

The association * * * between heart disease and silica risk can not, unfortunately, be measured directly, as the deaths ascribed either to silicosis or to chronic interstitial pneumonia are far too few to make this possible. It is worth noting, however, that there is a significant correlation between mortality (164 occupations) from bronchitis and chronic nephritis, $r = +0.380 \pm 0.045$. Chronic nephritis has been seen to be associated with heart disease, and bronchitis certainly often results from silicosis. If the latter is a cause of chronic nephritis, it may conceivably be a cause also of similar degenerative changes in the heart muscle. But association of these degenerative diseases may of course be independent of silicosis. Little more than vague speculation is possible without some more effective appraisement of the incidence of silicosis on occupations than is at present supplied by the mortality returns.

CEREBRAL HEMORRHAGE

A number of occupations have strikingly high rates from cerebral hemorrhage. The data are given in the next table.

TABLE 15.—*Standardized mortality from cerebral hemorrhage, etc., in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
13a	Tin and copper mine, underground workers, not superintending staff (III)	156.5
53	Cotton card and frame (not spinning frame) tenters (IV)	125.9
13	Tin and copper miners, not superintending staff (III)	122.6
36	Coppersmiths (III)	108.6
153	Barmen (IV)	77.0
152	Inn, hotel keepers, publicans (II)	72.6
156	Hairdressers, etc. (III)	68.3
60	Cotton weavers (III)	67.4
98	Painters and decorators (III)	64.8
124a	Salesmen, etc., in businesses for sale of fish, meat, green grocery, milk (III)	61.7
89	Employers, managers in the building, etc., trades, clerks of works (II)	59.4
42	Plumbers (III)	58.7
56	Cotton spinners and piecers (III)	58.5
11	Coal mine workers above ground, not superintending staff (IV)	57.6
9	Coal mine, persons making and repairing roads (IV)	56.1
112	Drivers of horse-drawn vehicles (IV)	54.1
8	Coal mine, persons conveying material to the shaft (IV)	52.9
123a	Proprietors, etc., of businesses for sale of fish, meat, green grocery, milk (II)	52.5
164	General and undefined laborers (V)	51.8
32	Machine tool workers and metal spinners (IV)	49.9
33	Fitters, tool setters, millwrights, and similar occupations (III)	47.9
	All occupied and retired males	41.1

It seems difficult at the present time to explain such extraordinary rates, several of them more than twice as high as that of all occupied and retired males, occurring in widely varying occupations.

It might be mentioned that the registrar general has determined the correlation between mortality from cerebral hemorrhage and that from chronic nephritis to be $.66 \pm .03$, emphasizing a point long understood in clinical medicine.

DIGESTIVE DISEASES AND CHRONIC NEPHRITIS

For brevity the next three tables are treated together.

TABLE 16.—*Standardized mortality from diseases of the digestive system in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
137	Barristers (I)	261.0
152	Inn, hotel keepers, publicans (II)	187.9
74	Brewers of ale, stout, and porter (IV)	170.5
153	Barmen (IV)	125.6
148	Actors (III)	119.6
140	Dentists (I)	101.1
160a	Warehousemen, textiles and clothing (III)	100.5
139	Registered medical practitioners (I)	86.6
122	Porters (V)	77.7
125	Commercial travelers (II)	76.6
123b	Proprietors, etc., of businesses for the sale of groceries and provisions (II)	75.8
123a	Proprietors, etc., of businesses for sale of fish, meat, green grocery, milk (II)	75.2
120	Other dock laborers (V)	72.4
123	Proprietors and managers of wholesale or retail dealing businesses (II)	70.1
112	Drivers of horse-drawn vehicles (IV)	67.4
46	Electrical engineers, fitters, and wiremen (III)	66.2
164	General and undefined laborers (V)	63.6
158	Clerks (not civil service or local authority); typists (II)	59.8
	All occupied and retired males	54.4

TABLE 17.—*Standardized mortality from peptic ulcer in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
137	Barristers (I)	157.9
153	Barmen (IV)	43.6
160a	Warehousemen, textiles and clothing (III)	37.6
152	Inn, hotel keepers, publicans (II)	26.4
112	Drivers of horse-drawn vehicles (IV)	22.4
46	Electrical engineers, fitters, and wiremen (III)	22.3
110	Railway porters and lampmen (IV)	22.0
164	General and undefined laborers (V)	19.2
	All occupied and retired males	14.5

TABLE 18.—*Standardized mortality from chronic nephritis in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
38	File cutters (III)	196.7
57	Wool and worsted spinners and piecers (III)	91.4
153	Barmen (IV)	81.2
152	Inn, hotel keepers, publicans (II)	71.5
156	Hairdressers, etc. (III)	60.9
42	Plumbers (III)	60.5
98	Painters and decorators (III)	60.1
123a	Proprietors, etc., of businesses for sale of fish, meat, green grocery, milk (II)	50.8
127	Costermongers, hawkers, and street sellers (V)	47.5
124a	Salesmen, etc., in businesses for sale of fish, meat, green grocery, milk (III)	47.3
56	Cotton spinners and piecers (III)	47.1
89	Employers, managers in the building, etc., trades; clerks of works (II)	45.5
123b	Proprietors, etc., of businesses for the sale of groceries and provisions (II)	44.8
29	Iron foundry furnacemen and laborers (IV)	44.1
112	Drivers of horse-drawn vehicles (IV)	41.4
123	Proprietors and managers of wholesale or retail dealing businesses (II)	40.6
164	General and undefined laborers (V)	40.0
	All occupied and retired males	31.6

It is difficult to separate the effect of specific occupational factors from the factor of intemperance in the case of these diseases. We find consistently high rates for publicans, brewers, barmen, porters, commercial travelers, etc., groups in which alcohol must be regarded as an important contributory factor and in which cirrhosis of the liver also shows a high mortality rate. Aside from alcoholic indulgence, dietary intemperance plays a part. Between the two the effect of any specific hazard is more or less obliterated. One is not sure, in examining the table for digestive diseases, whether these two points do not really explain every high rate. Few occupations show significantly high rates for ulcer of the stomach. The extraordinary rate for barristers, although significant as judged by the probable error, still contains a great deal of chance fluctuation, due to the small group. The probable error of the rate is 29.

In the case of chronic nephritis, the effect of alcoholism is pronounced, but other factors are at work, such as association with lead poisoning (plumbers, painters, and decorators). It might be stated that in all previous reports file cutters have exhibited definite mortality from lead poisoning, so that this association may be responsible for their position in this table.

No table has been prepared for diabetes, but it is of interest to note the high rates from this cause among glassworkers. Glass blowers, other skilled glasshouse workers, and other glass workers (i. e., not in the glasshouse) all have an unusual mortality from diabetes, a fact which appears to be very significant to the registrar general. He notices the fact that none of the deaths among glassworkers occurred at ages over 65, with 60 per cent at ages 55–64, which in itself may be significant of some occupational influence.

LEAD POISONING

No special table has been prepared for deaths from lead poisoning, because of the small number classified specifically under this heading (150 for the three years). These deaths were distributed as follows:

Potters	27
Plumbers	18
Occupations akin to plumbing	4
Painters and decorators	69
Other deaths probably due to paint	2
Workers in white and red lead	7
All other occupations	23

No new information as to lead hazard is contained in these figures. It should be observed that only one death was assigned to accumulator (battery) makers and pasters. However, the group is small and this occupation had not been pursued for very long when these returns were made (1921–1923). Even this one death gives a crude

rate of 73 while that for all occupied and retired males is little more than 1.

CANCER

The table for cancer follows:

TABLE 19.—*Standardized mortality from cancer (all sites) in occupations with rates above average, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	Mortality rate
154	Waiters (III)	235.3
75	Cellarmen (IV)	211.6
153	Barmen (IV)	210.3
56	Cotton spinners and piecers (III)	193.6
104	Gas stokers (IV)	187.7
122	Porters (V)	182.8
157	Chimney sweeps (III)	[1] 181.3
88	Bookbinders and pattern card makers (III)	176.9
149	Musicians (III)	176.8
40	Metal grinders (IV)	176.6
160a	Warehousemen, textiles and clothing (III)	175.9
35	Brass finishers and turners (III)	170.9
112	Drivers of horse-drawn vehicles (IV)	168.3
120	Other dock laborers (V)	167.2
164	General and undefined laborers (V)	162.1
115	Omnibus and tram conductors (IV)	155.4
152	Inn, hotel keepers, publicans (II)	149.8
124c	Salesmen, etc, in businesses for the sale of textiles and clothing (III)	148.6
25	Chemical workers (IV)	146.2
28	Metal molders (III)	145.5
125	Commercial travelers (II)	144.3
124a	Salesmen, etc, in businesses for sale of fish, meat, green groceries, milk (III)	143.3
162	Packers (IV)	141.2
27	Persons engaged in smelting, rolling, converting of iron and steel (IV)	135.8
31	Smiths and skilled forge workers (III)	131.2
	All occupied and retired males	117.5

[1] Difference is less than 3 times the probable error.

In view of present speculation as to the causes of cancer, its relation to occupation, is one of the deepest interest. The registrar general has appreciated this and gives to this disease a great deal of careful thought, and anyone working in this field should refer to the volume itself. Here it is possible only to point out what groups of workers have high rates from cancer.

1. Those exposed to soot and various coal-tar preparations (gas stokers, chimney sweeps).[11]

2. Those exposed to certain food and drink conditions (waiters, barmen, publicans). The registrar general suggests that cancer of the upper alimentary tract is largely influenced by food and drink. In connection with these occupations (and also cellarmen, porters, other dock laborers), it should be noted that Hope gives as one of the groups with high rates from cancer those having an excessive mortality from alcoholism.[12]

[11] The difference between the rate for chimney sweeps and that for all occupied males was not three times the probable error of the former, but was, nevertheless, included because of past experience and the fact that the rates in various ages are consistently higher for sweeps.

[12] Hope, Hanna and Stallybrass: Industrial Hygiene and Medicine, p. 414.

3. Those exposed to chemical fumes (chemical workers).

4. Those exposed to metallic dusts and fumes (metal grinders, brass finishers and turners, metal molders, persons engaged in smelting, rolling, converting of iron and steel, smiths, and skilled forge workers).

5. One specific occupational disease, cotton spinners' scrotal cancer. No satisfactory analysis is possible without consideration of site, and this is not possible in this review.

V. Summary of Standardized Rates by Occupation

By way of summary of the preceding tables according to important diseases, the rates have been assembled in a single table, the causes being placed in successive columns. Thus is permitted a picture of a fundamentally important fact—the relation of different causes of death in the same occupation. The occupations are arranged according to the order of mortality for all causes. As before, there are given only the rates in which the difference between the rate and that for all occupied and retired males is three times the probable error of the particular rate.[13] Also, as an abbreviation of the table, there are shown only occupations for which the rate for all causes is 10 per cent greater than that for all occupied and retired males.

TABLE 20.—*Standardized mortality, by occupation and cause, males aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	All causes	Respiratory tuberculosis	Bronchitis	Pneumonia	Influenza	Valvular heart	Other heart	Cerebral hemorrhage	Digestive diseases	Peptic ulcer	Chronic nephritis	Cancer (all sites)
13a	Tin and copper, underground (III)	3,966	1,886	227				195	157				
40a	Grinders, cutlery trade (IV)	3,015	1,179	331	190			170					
13	Tin and copper (III)	2,990	1,324	176					123				
40	Metal grinders (IV)	1,809	637	143	147			107					177
153	Barmen (IV)	1,789	403	91	149		117	108	77	126	44	81	210
38	File cutters (III)	1,694	365									197	
20	Earthenware, china, etc. (III)	1,674	336	222				127					
127	Costermongers, hawkers, etc. (V)	1,519	342	122	154			100				47	
18	Potters' mill workers, etc. (III)	1,502	411	247									
118	Stevedores (IV)	1,481	334		189								
53	Cotton, card, and frame tenters (IV)	1,465			170				126				
95	Slate masons and slate workers (III)	1,460	513										
152	Inn, hotel keepers, publicans (II)	1,450	201		125	51	77	109	73	188	26	71	150
120	Other dock laborers (V)	1,402	285	114	156					72			167
30	Brass foundry (IV)	1,400	318		194								
51	Cotton blow-room operatives (IV)	1,387		137	177								
75	Cellarmen (IV)	1,382	236					122					212
122	Porters (V)	1,370	269	99	139			98		78			183
41	Metal glazers, polishers, etc. (IV)	1,320	318	80				104					
164	General and undefined laborers (V)	1,316	247	88	181	45	87	77	52	64	19	40	162
160a	Warehousemen (III)	1,300	306							101	38		176
21	Other skilled glass workers (III)	1,296	270	113	134								
19	Pottery dippers, glaziers, etc. (III)	1,293											
55	Cotton strippers, grinders, etc. (IV)	1,277		253			120						
68	Hat formers, plankers, etc. (III)	1,277	260					139					
94	Masons, cutters and dressers (III)	1,272	304	91									
112	Drivers of horse-drawn vehicles (IV)	1,261	197	93	124	42	79	79	54	67	22	41	168
54	Wool, card, or frame tenters (IV)	1,256	238										
103	Shipyard laborers, etc. (V)	1,236											
74	Brewers of ale, stout, porter (IV)	1,232								171			
148	Actors (III)	1,222	229							120			
154	Waiters (III)	1,210	242		116								235
161	Drafters and brush makers (III)	1,208	356	115									
23a	Glass blowers, finishers (III)	1,202		146									
64	Dye mixers and dyers (IV)	1,193		91		60	86						

[13] In case of Class V occupations, the rate for that class instead of the rate for all occupied is used as the basis of calculation.

TABLE 20.—*Standardized mortality, by occupation and cause, males aged 20–65, 1921–1923, England and Wales*—Continued

Occupation group No.	Occupation	All causes	Respiratory tuberculosis	Bronchitis	Pneumonia	Influenza	Valvular heart	Other heart	Cerebral hemorrhage	Digestive diseases	Peptic ulcer	Chronic nephritis	Cancer (all sites)
35	Brass finishers and turners (III)	1,183	308	80	120								171
117	Bargemen and boatmen (IV)	1,180				56							
104	Gas stokers (IV)	1,179		96	123								188
37	Cutlers (III)	1,175	337

11	Coal mine, workers above ground (IV)	1,082		81	95	57	95		58				
123a	Proprietors, fish, meat, etc. (II)	1,075			95		72	98	53	75		51	
137	Barristers (I)	1,071						151		261	158		
66	Cutters of textile goods and clothing (III)	1,069	281										
76	Tobacco factory operatives (III)	1,052	300										
28	Metal molders (III)	1,040		78	133	47							146
157	Chimney sweeps (III)	1,027	240										
71	Skilled boot and shoe, not clickers, cutters (III)	1,025	272										
29	Iron foundry furnacemen, laborers (IV)	1,021		83	177	60						44	
48	Skilled lime and tanyard workers, etc. (III)	1,017	225										
125	Commercial travelers (II)	1,014						74		77			144
70	Boot and shoe clickers and cutters (III)	1,010	272										
57	Wool and worsted spinners and piecers (III)	1,009										91	
88	Bookbinders and pattern card makers (III)	1,005											177
162	Packers (IV)	1,004	199	63	96								141
142	Music teachers (II)	1,003											

What is perhaps most impressive is the number of occupations with excessive rates from several causes. The group of barmen, for instance, have rates which are significantly above the average for all occupied and retired males for every disease in this list except influenza. Although confusion in putting down the correct cause of death and difficulties as to which of two causes is primary must be regarded as a factor here, there still remains a real and important correlation as to many causes of death. In the case of myocardial (other) heart disease, cerebral hemorrhage, and chronic nephritis, a close association is to be found.

The importance of selection in determining the mortality rates by occupation is strikingly demonstrated in the case of drivers of horse-drawn vehicles—a large group with no specific hazard. Here every cause of death in the table shows a significant excess.

Another point of great interest is the fact that certain diseases, such as tuberculosis, bronchitis, pneumonia, and "other" heart diseases, contribute largely to the excessive rates in the occupations at the top of the table, whereas others, such as influenza, valvular heart, cancer, are more or less scattered through the table.

In the old occupational classification of the Census Bureau all pottery workers were grouped under the title "potters; earthenware, etc., manufacture." Now this group is subdivided into kiln and oven men and kiln setters and placers (Group 20); potters' mill workers, slip makers, and potters (Group 18); and pottery dippers, glazers, painters, decorators (Group 19). The first two have a very excessive mortality from all causes—1,674 and 1,502, respectively—while the third is 1,293. The kiln and oven men show a marked excess for respiratory tuberculosis, bronchitis, and "other" heart disease; the potters for tuberculosis and bronchitis. In the case of the dippers and glazers the rates for no particular cause are significantly high.

One may be surprised not to find medical practitioners in this list. Since this group falls in social class I and our criterion of significance was based on all occupied and retired males, it is clear that this group may have rates for certain diseases higher than the average of their own social class and still have been omitted from all preceding tables. The writer felt that there was no necessity for any particular study of class I occupations. As a matter of fact, medical practitioners form a group with specific industrial hazards due to close contact with disease. They have a standardized rate of 1,021 as compared with 812 for social class I. Such an excess would mean nothing in contrast to all occupied males, and it is one of the great advantages of the present volume on occupational mortality that this differentiation as to social class may be made.[14] The physician will be interested to observe how his mortality from different causes compares with that of other persons in the same social class. Accordingly, a table is included giving the ratio of the rate of medical practitioners to that of class I as a whole, by cause, with the standardized rates. Those significantly above the rates for class I are in bold face.

TABLE 21.—*Ratio of standardized rates for registered medical practitioners to corresponding rate for social class I, by cause*

Cause	Ratio	Standardized rate	Cause	Ratio	Standardized rate
Accident	205	74.8	Bronchitis	117	13.6
Pneumonia	176	44.7	Cirrhosis of liver	114	16.8
Suicide	174	113.4	Cerebral hemorrhage	113	40.9
All respiratory (except tuberculosis and influenza)	160	140.9	"Other heart"	111	70.7
Influenza	153	42.5	Peptic ulcer	111	14.5
Chronic nephritis	138	43.3	Circulatory	101	180.4
All causes	126	934.0	Cancer	99	93.1
Digestive	125	86.6	All heart	99	96.2
Diabetes	125	17.4	Respiratory tuberculosis	95	69.2
Syphilis, etc	125	22.6	Appendicitis	93	12.8
			Valvular heart	77	25.4

[14] It was possible only in a limited way on the basis of the 1910–1912 occupational data.

Aside from the high ratio for accidents, what stands out above all is the high mortality rate for pneumonia, influenza, and the "all respiratory" group as a whole in relation to the corresponding rates for class I. Contact with cases of these diseases may be partially responsible. The ratios emphasize the highly communicable nature of influenza and pneumonia. Bronchitis is much further down the list, and there is no excess at all in the case of respiratory tuberculosis.

The high rate for accident is a little puzzling, but is perhaps associated with the constant use of the automobile by the physician.

A careful examination of the table summarizing the significantly high rates by occupation, suggests that in many instances the high death rate from all causes is not to be explained by the few diseases showing a significantly high mortality. Sometimes, indeed, no cause stands out at all. This does not necessarily mean that other causes than those given in the table explain the high rate, but rather that there is some excess in these causes, but not sufficient to be significant according to the criterion used. This will be true especially of the smaller occupations.

To bring out such relations, and also because of the convenience in comparing figures proportional to the rates for all occupied and retired males, an additional table is given, with the ratios to the rate for all occupied and retired males for each major cause (the so-called "comparative mortality figures" of the British report). The ratios are of two classes:

(*a*) Those in boldface are used wherever the rate is significantly high, or in other words, in every case where a figure was used in the preceding table:

(*b*) All other ratios for the occupations used in the preceding table based on 10 or more deaths. The limitation as to number of deaths was necessary to avoid too much meaningless fluctuation of the ratios.

TABLE 22.—*Ratio of standardized rates for specific occupations to that for all occupied and retired males, by major cause, where rate is above average based on 10 deaths or more, males, aged 20–65, 1921–1923, England and Wales*

Occupation group No.	Occupation	All causes	Respiratory tuberculosis	Bronchitis	Pneumonia	Influenza	Valvular heart	"Other heart"	Cerebral hemorrhage	Digestive diseases	Chronic nephritis	Cancer (all sites)

By way of interpretation of this table and also to describe briefly occupations which appear frequently in the previous tables, the following summary by occupation is provided. The text of the registrar general's report is drawn upon freely in discussing each occupation.

Tin and copper miners.—Such miners are found exclusively in Cornwall. There is some transfer between these fields and the Transvaal, so that some of the high mortality may be the result of working outside of England. In addition, the tin and copper mines were in a depressed condition in 1921, so that it is probable that most of the able-bodied men had left the mines. As stated before, it is now possible to separate the group of underground workers (13a) from the others and reveal the severity of the hazard. The high rates are found particularly in the case of respiratory tuberculosis, bronchitis, other heart diseases, cerebral hemorrhage, and cancer.

Metal grinders.—Again here it has been possible to separate the group with the greatest hazard (cutlery grinders) from the others. The high mortality for tuberculosis, bronchitis, pneumonia, other heart disease, and cancer in the total group is primarily due to that among cutlery grinders who form one-fifth of the total.

Publicans, barmen, waiters.—Barmen and publicans (including inn and hotel keepers) form a group with excessive mortality from nearly every cause. The distinctive feature of this mortality is perhaps that from cirrhosis of the liver (which is not given in the table), because of its clear indication of the effect of alcoholic intemperance. Except for occupations with known specific hazards, the occupation of barmen stands at the top. Of the diseases in the list, influenza is the only one which is not significantly above the rate for all occupied. Publicans are not much lower, and in that case every disease is significantly above all occupied except bronchitis. This is of particular importance, since this group is in class II, where the rates are usually lower than for all occupied. Waiters have been included for convenience, but they exhibit a much lower rate of mortality, the excess being confined to respiratory tuberculosis, pneumonia, and cancer.

File cutters.—Although a very small occupational group, these workers have been kept separate because of a very high mortality. Rapid change is believed to be in progress in the processes of manufacture, which appears to be reducing the risk for the occupations. For all causes the ratio to all occupied was 185 for 1921–1923. The rate for chronic nephritis was the highest of any occupational group, the ratio being 623. Only one other cause showed a significantly high rate—respiratory tuberculosis—the deaths from other causes being too small for analysis separately.

Makers of bricks and pottery.—These occupations may be combined for convenience, but include some where the conditions are not unfavorable and some where specific hazards exist. Some discussion of the occupations has already been given (p. 1595). The kiln and oven men and the potters have the highest rates. In both of these occupations the ratios are higher for bronchitis (489 and 543, respectively) than for any other major causes, and respiratory tuberculosis ranks next higher. "Other" heart condition is significantly high for kiln and oven men. Pottery dippers and glazers have a high ratio from all causes of 141, which may be explained by the rates for respiratory tuberculosis, "other" heart, and cancer; although in no case can these rates be shown to be significantly greater than those for all occupied. "Other" persons in the manufacture of bricks, etc., have a mortality ratio for bronchitis of 264, no other ratio being definitely significant.

Costermongers.—Costermongers are itinerant vendors of goods, working on their own behalf, instead of for employers, like the canvassers. Their high mortality rates are no doubt to be explained partly by reason of excessive alcoholism (the rates for cirrhosis of the liver are excessive), partly by reason of the physical type going into the occupation, partly, possibly, by reason of the severe weather conditions that the group is exposed to. The rates are high for respiratory tuberculosis, bronchitis, pneumonia, "other" heart, and chronic nephritis. Bronchitis shows the highest ratio. From other causes there seems to be little excess (influenza gives a ratio of 109, cerebral hemorrhage of 102, cancer of 121, digestive of 127). Thus the group stands out from those showing a consistent excess from every important cause.

Dock laborers.—In this group stevedores and coal-boat loaders and dischargers have been tabulated separately. The latter have much lower mortality rates than the dock laborers as a whole (the ratio being 123, while that of stevedores is 162, and of "other" dock laborers, 153), and are too small a group for any particular study of individual causes of death. Bronchitis and pneumonia are highest. Stevedores also comprise a small group; but in spite of this fact we find significantly high rates for respiratory tuberculosis and pneumonia, with a rate for bronchitis which is more than twice that of all occupied (though not quite three times the probable error). "Other" dock laborers comprise a large enough group for more precise comparison. The death rates are significantly high for respiratory tuberculosis, bronchitis, pneumonia, digestive, and cancer. It should be added that in the case of stevedores comparison is made with all occupied, because the group does not fall in social class V, but in the case of coal loaders and "other" dock laborers the test of statistical significance is made with Class V. One can hardly avoid the im-

pression that the exposure of these men to inclement weather has something to do with the very marked excess of mortality from respiratory conditions.

Cotton workers.—Different occupations among cotton workers have already received some consideration in relation to bronchitis and respiratory diseases in general. The group deserves careful study with a detail that is not possible in this paper. Both dust and high temperature and humidity are occupational hazards, but there are suggestions in the data that selection of an inferior type physically and other factors may be of great importance in determining the death rates. The same factors appear to have major influence in the cotton industry in the United States. The disease which stands out most prominently is bronchitis, with a ratio of 558 for strippers and grinders; 302 for blow-room operatives; 196 for doublers, winders, etc.; 143 for spinners and piecers. It is noteworthy that there is no excess for respiratory tuberculosis in any of the specific occupations. Owing to the small numbers in the groups (except spinners and doublers), it is difficult to reach a conclusion as to other causes of death; but ratios are almost invariably above 100. Spinners show a general excess from nearly every cause, no one disease predominating; so in lesser degree with doublers. Weavers are not included in the table, as the rate for all causes was not 10 per cent in excess of the corresponding rate for all occupied.

Masons, stonecutters, and dressers.—The workers of one specific occupation may be considered first, slate masons and workers, who have a very high mortality rate, primarily from respiratory tuberculosis, for which the ratio is 343. The relation to silica dust is established for this occupation. The group is a small one, limited to one district of North Wales.

Although masons, stonecutters, and dressers have been grouped together, whether working in limestone or sandstone, it is clear that a differentiation between the two is necessary if the data are to have much meaning. It will be recalled that such a separation was made in the table on chronic interstitial pneumonia. For the whole group a significant excess is found for respiratory tuberculosis and pneumonia, the other rates being close to the normal. From all causes, sandstone masons show a ratio of 207 and limestone masons a ratio of 120.

Brass foundry.—Brass foundry furnace men and laborers are subject both to the heat risk of foundries in general and to the special risk associated with molten brass. The significantly high rates in this group are from respiratory tuberculosis and pneumonia; but those from bronchitis (199) and cerebral hemorrhage (206) are also suggestive. The ratio for all causes is 153.

Brass finishers and turners may be mentioned here, although they work in cold metal. Significantly high rates are found from respira-

tory tuberculosis, bronchitis, pneumonia, and cancer; but the ratio for all causes is much less (129) than that for the furnace men. Exposure to dust during processes of sand grinding and polishing may contribute to the mortality among finishers.

Porters.—Porters are classified in social class V, but have rates significantly above those for that class from respiratory tuberculosis, bronchitis, pneumonia, "other" heart, digestive, and cancer. The group is no doubt affected to a considerable extent by alcoholism, and shows excessive rates for cirrhosis of the liver.

Messengers, hall porters, etc., are chiefly boys under 20 years of age, and therefore the standardized figure for them is somewhat dubious. Nothing stands out as significant. The majority are classified in social class V, and thus the ratio for all causes (120) conforms to that of their social class.

Metal polishers.—As polishing may be looked upon as a modified form of grinding, so the mortality of polishers presents similar features to that of grinders in a somewhat lesser degree. The rates are significantly high for respiratory tuberculosis, bronchitis, and "other" heart. The pneumonia and influenza rates may also be of importance.

General and undefined laborers.—High mortality is natural to this group, for ill health, misfortune, and unreliability of character must all combine to recruit its ranks. The rates are significantly above social class V for every cause of death in the list, but because of the large numbers in the group only a small excess is needed to show a significant difference. The diseases, in the order of the ratios, are as follows: Bronchitis, pneumonia, respiratory tuberculosis, valvular heart, cancer, influenza, chronic nephritis, "other" heart, cerebral hemorrhage, digestive.

Warehousemen (textiles and clothing).—Warehousemen in general do not have much excess mortality, but those in textiles and clothing have an excess for all causes of 42 per cent, with significantly high rates from respiratory tuberculosis, digestive, and cancer.

Skilled glass workers.—The three groups in which glass workers are divided are meant to include all workers who can be assumed to be subject to the intense heat of the glasshouse—skilled glasshouse workers (Group 23); one special subdivision of these, glass blowers by the traditional method (Group 23a); and other skilled glassworkers, who work mainly in cold glass (engravers, cutters, bevelers, optical workers, etc.) (Group 24). The ratios which are significantly high for these three groups are as follows:

Group 24, respiratory tuberculosis (181), bronchitis (250), pneumonia (172).

Group 23, respiratory tuberculosis (144), bronchitis (265).

Group 23a, bronchitis (322).

The registrar general records as remarkable the high mortality from diabetes among glassworkers (a disease which has not been included in this review). All three of these groups are near the top, 23a and 23 being first and second, respectively. However, the only rate of the three which is significantly high as judged by the probable error is that for skilled glasshouse workers.[15]

Hat formers, plankers, stiffeners.—Two rates are significantly high (respiratory tuberculosis and "other" heart). For cancer, the ratio is 162, but the difference between the rate and that for all occupied is not three times the probable error. There were four deaths.

Drivers of horse-drawn vehicles.—These are almost all engaged in the transportation of goods. The "coachman" of former days has practically disappeared. The rates are significantly above all occupied for every cause considered in this paper, the highest ratio being that for bronchitis. What is of particular interest is that motor drivers do not show any general excess at all. It may be difficult to assign definite reasons for the consistently high rates among drivers of horse-drawn vehicles. Certain it is that no specific hazards exist, unless we regard inclement weather as such. It is hard to escape from the conclusion that a selective process, aided by the fact that the occupation is to be regarded as gradually being replaced by that of motor drivers, has been at work, leaving a group inferior physically.

Wool industry.—Wool, card or frame, tenters have a ratio for all causes of 137. The rate for respiratory tuberculosis is significantly high. That for bronchitis, although not significant according to the criterion used, gives a ratio of 218. Wool sorters and rag winders and wool willowers appear near the bottom of the table, and in neither is any individual ratio significantly high. Wool and worsted spinners and piecers, although with a low ratio for all causes, have a significant ratio of 290 for chronic nephritis.

Shipyard laborers.—This group comprises all the unskilled workers in shipbuilding who could not be assigned as unskilled workers in the metal-working, woodworking, or painting sections. The group falls in social class V, and the rates for no apparent cause are significantly above the corresponding rates for that class.

Actors.—Respiratory tuberculosis and digestive diseases have significantly high rates for this occupation. Cirrhosis of the liver (not given in the table) indicates the effect of alcoholism in this group.

To save space, this description of occupations will not be carried down to those with only slight excess above the rates for all occupied. Some hazards are no doubt present in a few of these occupations, and it is not meant to imply that there is not a great deal of information

---

[15] Group 23a has a mortality rate of 42 4 $\pm$ 11 3, Group 24, 28.7 $\pm$ 7.6. All occupied is 11.2.

of interest in this part of the table; but space forbids any detailed consideration.

VI. Mortality by Age from a Few Causes

For purposes of any extended analysis, perhaps the most valuable portion of the registrar general's report lies in the "abstracts" giving the deaths and the death rates by age, cause, and occupation. From such sources it is difficult to identify hazards in small occupational groups, as noted above; but the material is immensely valuable as reflecting the effect of industry on the health of the workers in a general sense, and the different ways in which this influence is felt in specific diseases. It is not possible here to more than touch upon some of the points of greatest interest. Because of the unique position occupied by respiratory tuberculosis, that cause of death has been selected for special study, but tabular data are also given for a number of other diseases.

TUBERCULOSIS

The extraordinary decline in mortality from tuberculosis in recent years might suggest that this disease had ceased to be of fundamental importance in industry, but, as the preceding tables have shown, this is not at all true. A series of graphs are given, in which the age curve of respiratory tuberculosis for a number of occupations is contrasted with that for all occupied and retired males. Quite obviously, only occupations of considerable size could be used, since in other cases the rates by age would fluctuate widely. Hence the graphs can not be taken as a complete picture of occupations with excessive death rates from respiratory tuberculosis. For such a picture it is necessary to turn back to Table 7. In the case of occupations in class V, it has been found well to include the curve for that social class. The rates in class III and class IV were so nearly the same that it seemed preferable, generally, to use the curve for all occupied and retired males. At the end of the series of graphs is given also the curve for farmers. The occupations are arrayed according to the magnitude of the death rate. For the first graph a scale one-fourth that used in succeeding graphs was deemed necessary. The reader must bear in mind that many abrupt changes and irregular fluctuations in the curves are due to the small numbers. It will be found difficult to extract any meaning except from the general trends.

Where there is a specific hazard, there is a tendency for the rate to rise steadily with age, quite unlike the rate for occupied males generally. This unique form of curve is noted particularly for tin and copper underground miners; grinders in cutlery trade; slate masons and slate workers; potters' mill workers and potters; cutlers;

masons, stone cutters, and dressers; earthenware, china, etc., kiln and oven men, and kiln setters and placers; slate miners and quarriers. One is impressed here by the unique position held by dust, particularly dust with a high percentage of free silica.

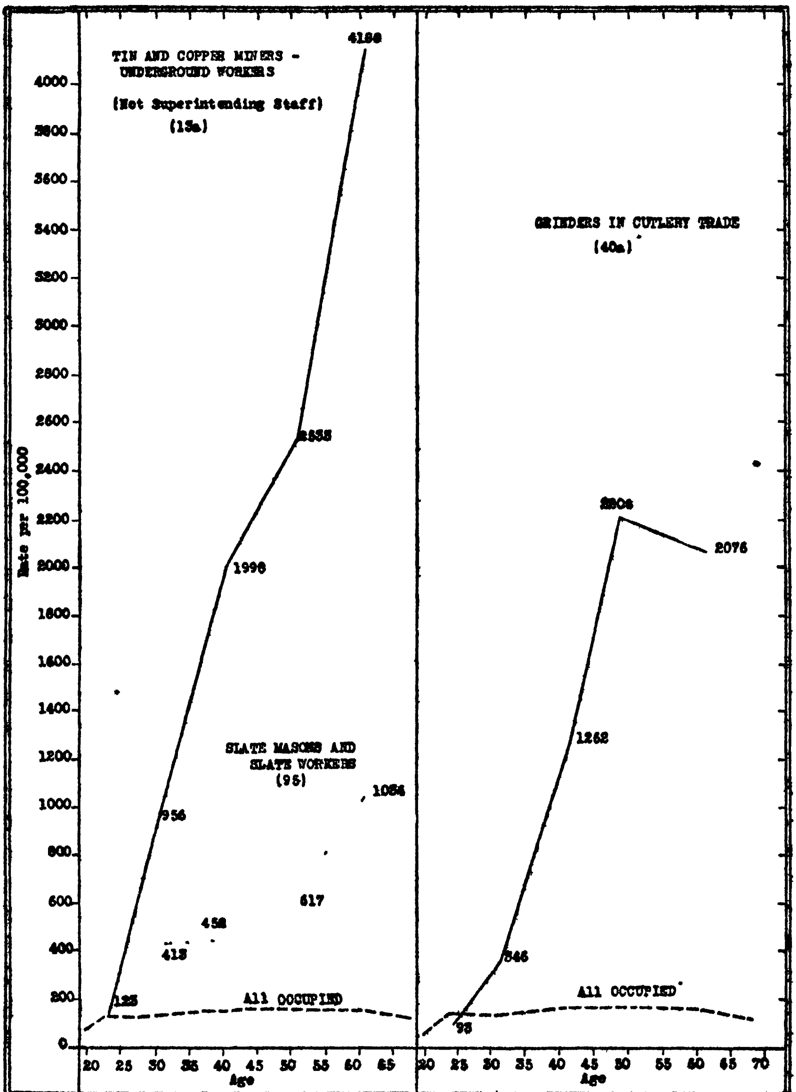

FIG 1 —Mortality rates for respiratory tuberculosis for males in specified occupations and for all occupied and retired civilian males, by age, England and Wales, 1921–1923

But in many other occupations where dust is not a factor, abnormally high mortality rates from respiratory tuberculosis are found. The shape of the curve in these occupations has a tendency more or less to follow that of the curve for all occupied, but important

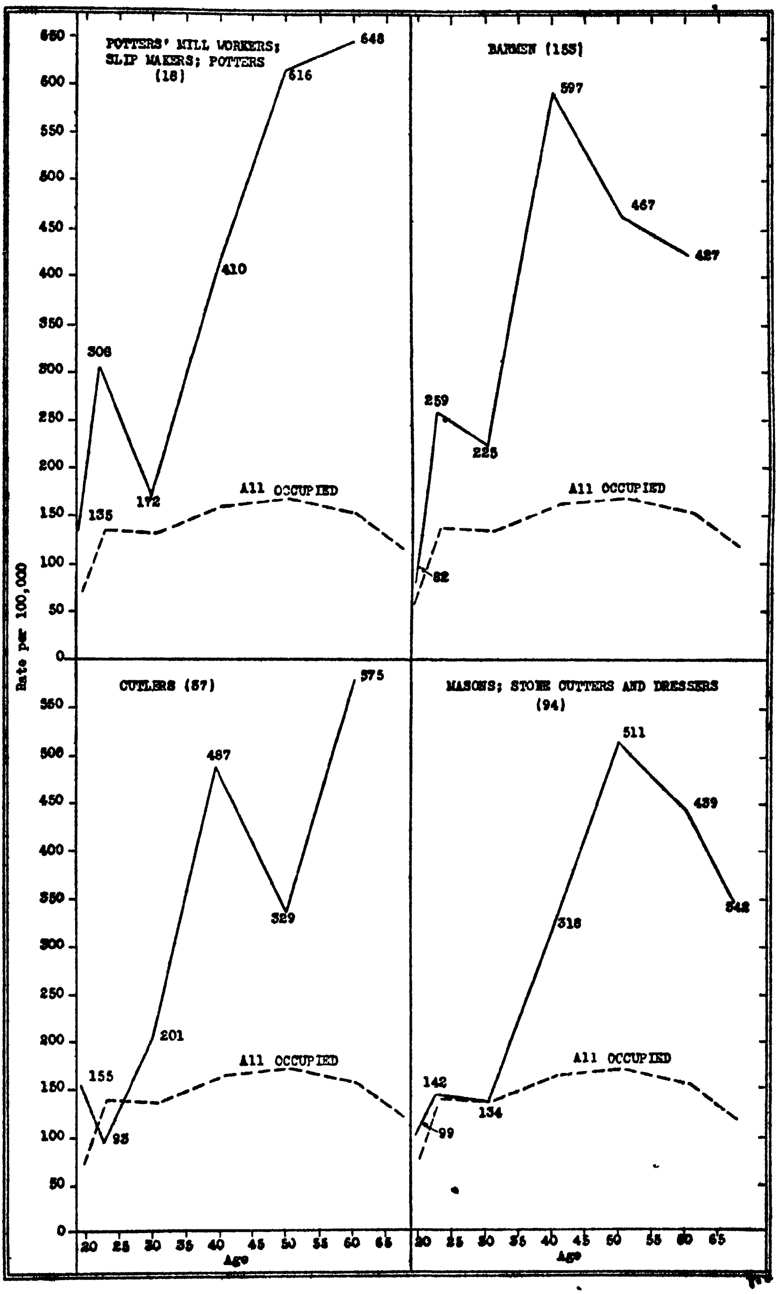

FIG 2.—Mortality rates for respiratory tuberculosis for males in specified occupations and for all occupied and retired civilian males, by age, England and Wales, 1921–1923

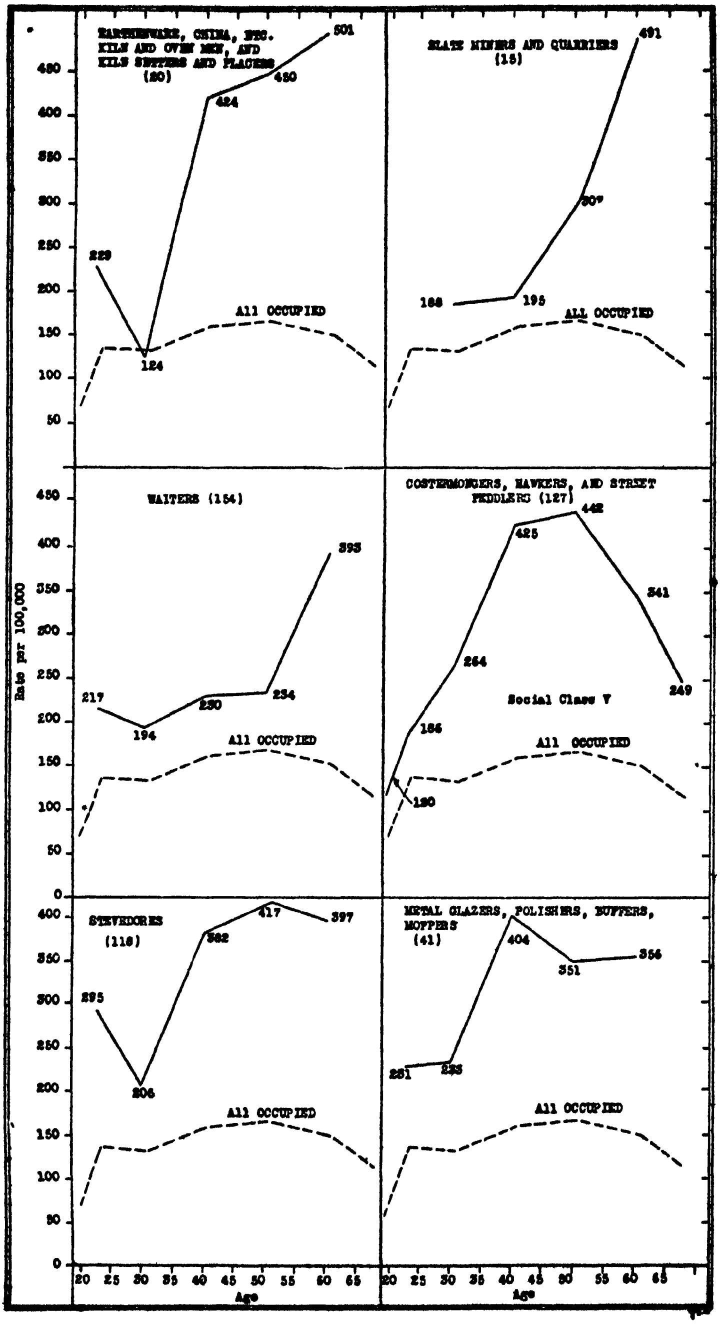

FIG 3 —Mortality rates for respiratory tuberculosis for males in specified occupations and for all occupied and retired civilian males, by age, England and Wales, 1921-1923

differences are manifested. In some occupations the death rate appears to be higher than the average from the beginning of life on, suggesting a selective factor in the type of worker rather than the

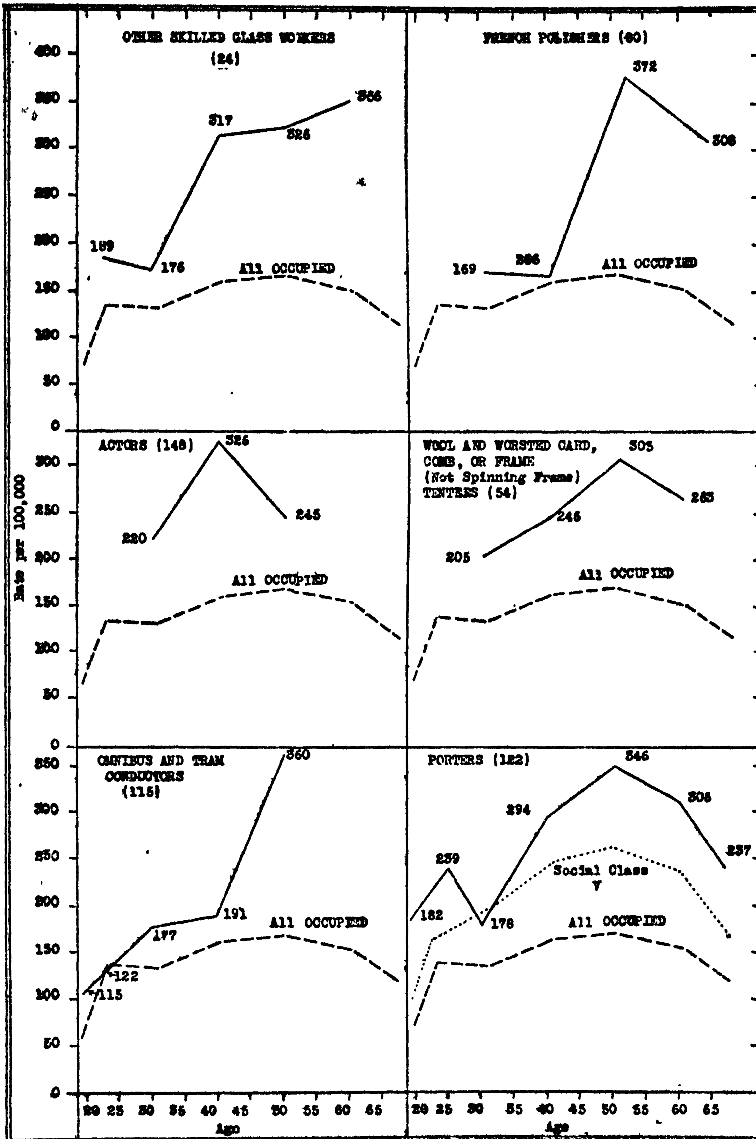

FIG. 4.—Mortality rates for respiratory tuberculosis for males in specified occupations and for all occupied and retired civilian males, by age, England and Wales, 1921–1923

effect of any hazard. In other cases the curve is no higher at the beginning of life, but reaches a peak later, and then gradually declines. One feels that in some occupations there are reflected such indirect

hazards as the strain of the industry or possibly exposure; in others that "the conditions of life implied by various occupations," as the registrar general puts it, appear to be of greatest importance. This

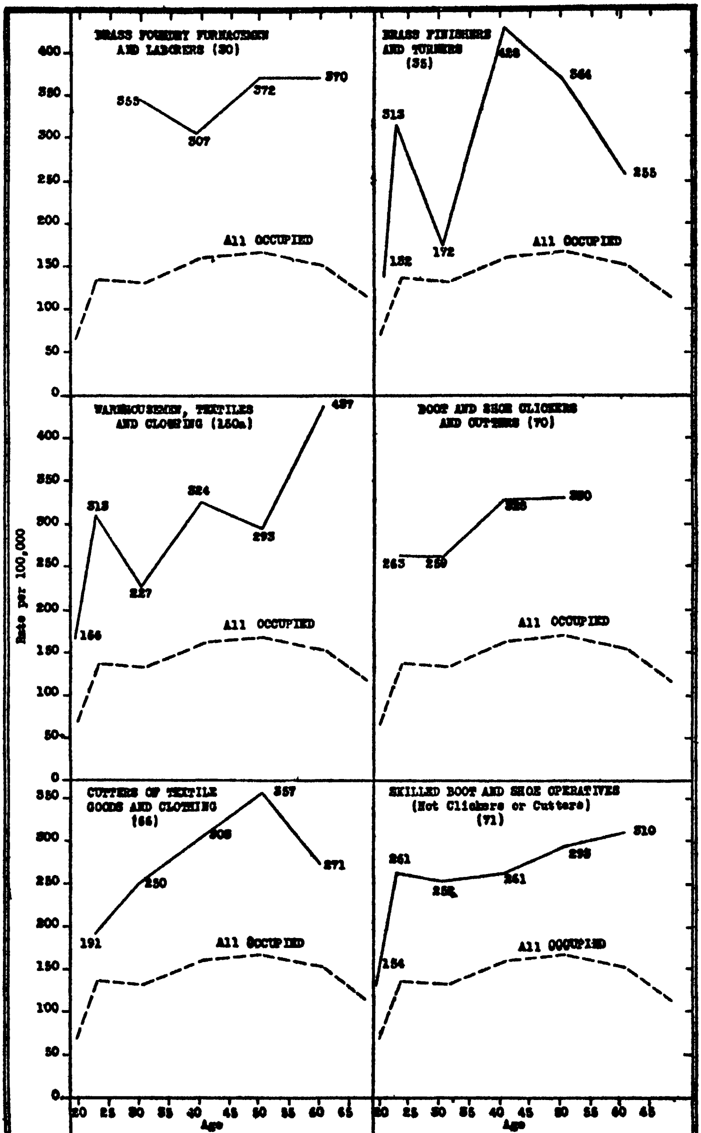

FIG 5 —Mortality rates for respiratory tuberculosis for males in specified occupations and for all occupied and retired civilian males, by age, England and Wales, 1921-1923

series of graphs suggests the need for an adequate study as to the causes of the high tuberculosis mortality in industry, apart from specific hazards.

OTHER MAJOR CAUSES OF DEATH

Respiratory tuberculosis lends itself peculiarly well to a comparison by age. Other major causes of death have relatively little mortality

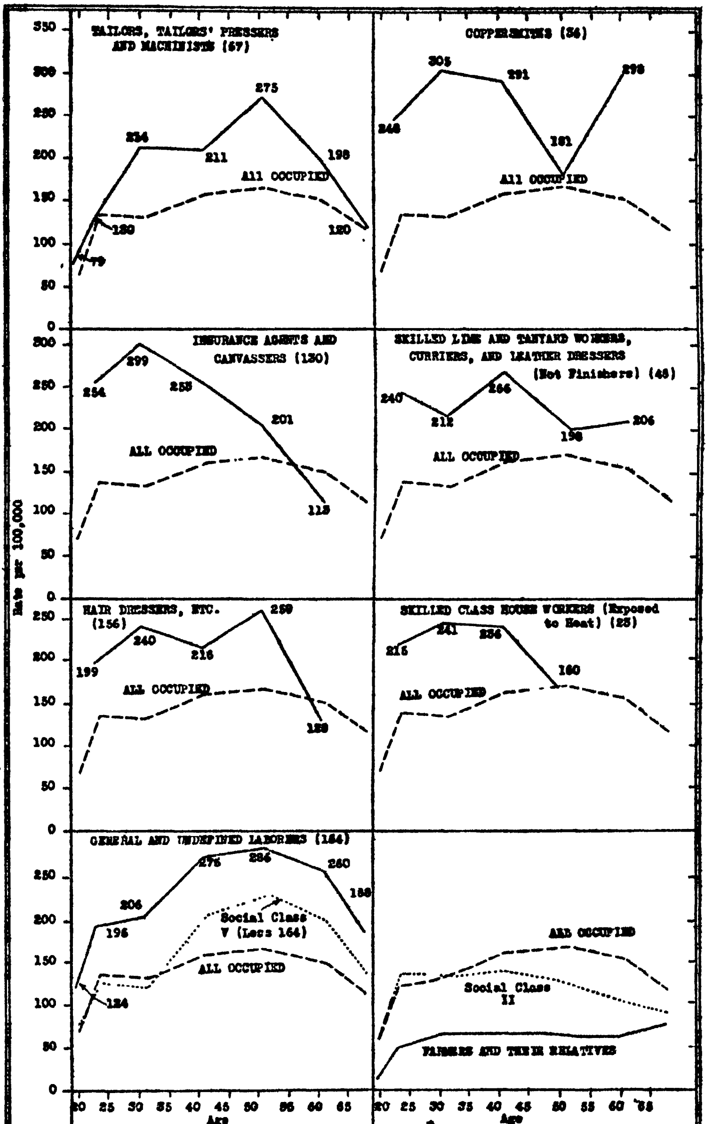

FIG. 6.—Mortality rates for respiratory tuberculosis for males in specified occupations and for all occupied and retired civilian males, by age, England and Wales, 1921–1923.

in the younger ages. Accordingly, a graph would fail to bring out important differences at these ages, because such differences would be overshadowed by the height of the curve in advanced age. Tables

of the rates themselves, with ratios to the rate for all occupied in the same age group, seem to give a better idea of the influence of occupation. Such tables have been prepared for the following diseases: Bronchitis, pneumonia, valvular heart disease, other heart disease, cerebral hemorrhage, chronic nephritis, and cancer. Except in the case of pneumonia, satisfactory rates can be obtained only for three age groups, 35–44, 45–54, and 55–64. Rates for the lower ages are usually based on too small a number of deaths for satisfactory interpretation; rates for the ages beyond active industrial life, as in previous tables, do not seem to have any definite meaning with respect to occupational differences. Only occupations with significantly high rates and with large enough populations to permit fairly stable curves by age are included. The standardized rates and the rates for the three age groups are given at the top of the table, followed by corresponding ratios to the rate among all occupied and retired males. Blanks are left where the number of deaths is quite small. Such comment as seems necessary is given at the end of the whole group of tables.

TABLE 23.—*Mortality by age from bronchitis in occupations with excessive*[1] *rates, including ratio to rate among all occupied and retired males*

	Standardized rate	Age group		
		35–44	45–54	55–64
RATE PER 100,000

[1] Where numbers are sufficient for specific rates.
[2] Difference less than 3 times the probable error.

Occupations with the highest mortality from bronchitis tend to show progressively higher rates as age advances, paralleling what was found in the case of tuberculosis. For instance, potters have a ratio of 366 for age group 45–54 and 695 for age group 55–64. In the case of cotton strippers the two rates are respectively 525 and 654. The other occupations shown in the table, however, do not generally manifest this tendency. The striking differences as to mortality by social class brought out previously is reemphasized at the top of the table.

In the case of pneumonia it appeared that the data for the age group 25–34 was also of value, because of the relatively higher mortality at this age for pneumonia than for the other causes of death included in these tables. Pneumonia is an acute disease, and one would not expect an excessive rise with age even in occupations predisposing to the disease. The ratios suggest that the excess mortality occurs more or less indifferently throughout the ages considered.

The same impression is given by the ratios of valvular and other heart disease, in spite of many irregularities for specific occupations, and the remaining causes of death for which ratios have been calculated. Careful study of these ratios will no doubt reveal some points of real interest in connection with the manner in which industrial hazards and industrial strain reveal themselves in different diseases.

Conclusion

No summary of the rather variegated findings of this paper seems required. Certain specific hazards have been thrown into relief by these figures, hazards which were in most cases understood to exist. In some instances new emphasis has been placed upon them; in others a different evaluation. From the point of view of specific, direct occupational hazard, it seems to the writer that the material is particularly valuable as an aid in checking up the meaning and extent of conditions which an industrial hygienist may encounter in his own work. If some adverse influence is suspected, the British figures may throw light on whether a suspected association between the condition and the occupation itself may be real.

Beyond this realm of direct deleterious influences (which really affect a relatively small group of the working population) we see the subtle and pervasive effect of many indirect conditions, occupational, living, even hereditary. "It will be found," states the registrar general, "that the effect of occupation upon male mortality is probably on the whole more indirect than direct—that mortality is influenced more by the conditions of life implied by various occupations than by the direct occupational risks entailed. The figures for

males do not permit of differentiation between the two types of influence, as both are at work in every case, so no definite proof can be adduced of this suggestion, which merely represents an impression created by study of the facts dealt with."

PUBLIC HEALTH ENGINEERING ABSTRACTS

Contact Infection of Milk Through Bottles. R. Meurer. Ztschr. f. Fleisch-u. Milch-hygiene, 1927, v. 37, 150–153; 169–172. From *Bulletin of Hygiene*, vol. 3, No. 1, January, 1928, pp. 21–22.

"Results of bacteriological examinations show progressive increase in the bacterial content of milk from the time of milking until finally bottled for delivery.

"Two samples tested showed an increase from 97 per cent to 442 per cent in the bacterial content. The large increase took place in the final stage of bottling.

"A completely sterile flask is difficult to obtain, so it is of great importance that preliminary stages in milking should be done with more care."

Sources of contamination: (1) "A large number of bacteria are to be found in water used for rinsing the vessels; (2) the brushes used for cleansing the vessels are potent sources of contamination and a larger increase in the bacterial content occurs in the milk if old brushes are used than with new brushes; (3) * * * 400,000 bacteria per c. c. were found in bottled milk, whereas directly after the cooling process the number was only 5,000 per c. c.; (4) * * * when samples of pasteurized milk were placed in sterile vessels and the ordinary bottles, the bacterial content of the milk in the sterile bottles remained constant, while that of the ordinary bottle varied greatly."

Reducing contamination: (1) "If the bottles are dried at 70° C. (158° F.) for thirty (30) minutes after they have been rinsed, the number of bacteria in the milk is greatly reduced; (2) in order to ensure a low bacterial content, bottles should be filled as soon as possible after sterilization of the milk; (3) * * * placing bottles in inverted position reduces contamination."

Chemical Sterilization in the Dairy Industry. M. J. Prucha. World's Butter Rev. 2, 12–7 (1928). Abstract by F. L. Seymour-Jones in *Chemical Abstracts*, vol. 22, No. 8, April 20, 1928, p. 1414.

"The Cl group of disinfectants is most satisfactory for dairy equipment. Cl in aqueous solution, $Ca(OCl)_2$, NaOCl dry and in solution, and chloramine-T were studied. All solutions were fairly stable up to 60 minutes at 26–71°. The addition of small amounts of milk caused reduction in available Cl, increasing with milk concentration. Adding NaOH increased stability except in the presence of milk, when decomposition was more rapid. Laboratory tests on *B. coli* showed sterilization was satisfactory with Cl and hypochlorites; with chloramine-T greater concentrations of available Cl were necessary. NaOCl gave excellent results in a four-month test in a bottled-milk plant. All utensils and equipment should be washed before sterilization. They are then rinsed with solutions of 50–100 p. p. m. available Cl or sprayed with solutions of 500 p. p. m."

Eliminating Tastes and Odors Caused by Algae in Water. Chester Cohen. *The American City*, vol. 38, No. 4, April, 1928, pp. 129–130. (Abstract by J. B. Harrington.)

Algae in Southern States, where climatic conditions are favorable to their growth, are partly responsible for discoloring the water, for imparting tastes and odors to the water, and for clogging filter beds and filling the pores of the filter material. Their presence is also quite common in swimming pools. Living

algæ produce oils which give the water a fishy, grassy, oily taste. When the food supply becomes exhausted and the algæ die, or when the algæ are killed by treatment, decomposition takes place, producing a strong medicinal taste when chlorine is used.

Algæ may be controlled by covering the reservoir or by treatment of the water with copper sulphate (bluestone) or chlorine. The dosage of either must be determined according to the type of algal growth. Water weeds in large reservoirs are usually destroyed by cutting the tops below the water line or by pulling up the weeds.

The Relation of Turbidity to Coagulant Dosage. Kenneth C. Armstrong. *The American City,* vol. 38, No. 2, February, 1928, pp. 100–102. (Abstract by J. B. Harrington.)

In this paper is described the relation of the turbidity to the coagulant dosage as observed at the Omaha, Nebr., filtration plant. From a series of tests, made by permitting river water to settle in a 5½-foot glass cylinder for various lengths of time and then siphoning off samples for turbidity tests, it was found that the coagulants required could be determined by the results of the three-hour settling tests.

During periods of high turbidity (10,000 p. p. m.) the application of coagulants at two points has been extremely helpful in delivering a satisfactory water to the filters. The effect of various turbidities on the coagulants required and the results of the settling tests are given in detail and shown on various charts of operation for June and July, 1926, and May, 1927.

The following conclusions are given: (1) The suspended material is chiefly responsible for variation in coagulant dosage; (2) coagulant dosage can be determined largely by the results of the 3-hour turbidity test; (3) two-point application of chemicals is helpful in treating very turbid water; (4) the 24-hour turbidity test gives a good indication of the concentration of finely divided material, some of which is of colloidal nature.

The Twort-D'Herelle Phenomenon. R. Bruynoghe. *The Journal of State Medicine,* vol. 35, No. 11, November, 1927, pp. 621–636 (Abstract by C. T. Butterfield.)

The author discusses the subject under the following headings: (1) Historical; (2) means of detecting bacteriophage; (3) the resistance of germs toward bacteriophage influence; (4) the properties of bacteriophages; (5) plurality of bacteriophages—(*a*) reciprocal resistance, (*b*) neutralization of bacteriophages, (*c*) properties of the bacteriophages; (6) the bacteriophage complexity.

The literature related to each type is reviewed briefly. The article is to be continued in subsequent numbers of the *Journal.*

McQueen vs. Owen Sound and Others. Anon. *Canadian Engineer,* vol. 54, No. 1, Jan. 3, 1928, pp. 111–113; No. 2, January 10, 1928, pp. 124–126. (Abstract by R. E. Thompson.)

In the case of McQueen *v.* the City of Owen Sound in 1926 the trial court found that "the plaintiff's illness [typhoid] was caused by the negligent supply to her by the defendants of contaminated water and awarded her damages" [$2,000].

The defendants appealed, and the conclusions of the appeal court are summed up as follows: "First, that there is no direct evidence that the water supplied the plaintiff by the defendants carried typhoid bacilli and that there is no indirect evidence to warrant the inference that it did; therefore it could not have caused her illness. On this ground alone her action fails. Secondly, I am of opinion that even if the water did contain typhoid bacilli the evidence does not warrant the inference that of all possible causes of the plaintiff's illness the most probable one was contaminated water. For this reason also her action fails, and

the judgment should be set aside and the action dismissed with costs below and of the appeal."

It is believed by the appeal court that not sufficient importance was attached to the possibility of contamination carried by flies from neighboring septic tanks, the overflow from which flowed in an open ditch in the vicinity of the plaintiff's residence. The case under consideration was one of a number which occurred in a restricted area. Of 800 pupils attending two schools in the district which was supplied with the same water as the plaintiff, only 3 contracted the disease, and these three pupils resided in the area in which infection from the septic tanks was possible. A previous outbreak in another section of the city may have been caused by fly or air borne infection from sewage sludge recently distributed over an area of land.

Clarification of the Catskill Water Supply of the City of New York by Coagulation and Sedimentation. Wm. W. Brush. *Journal of the New England Water Works Association*, vol. 42, No. 1, March, 1928, pp. 65–78. (Abstract by W. J. Scott.)

In December, 1926, a combination of very low storage-reservoir level with a flood-flow run-off from watersheds containing many steep clay banks raised the turbidity of the Catskill water supply of New York City to such an extent that alum and soda-ash treatment was carried out for nearly six months. The chemicals were applied to water above Kensico Reservoir, having at times a turbidity of over 100 p. p. m., and clarification took place in Kensico Reservoir, where the maximum turbidity of the effluent was 7 p. p. m. Low hydrogen ion figures were recorded until soda-ash application was begun. A noteworthy feature was the rapidity with which the clarification of the turbidity in the untreated water of Ashokan Reservoir took place in the last two weeks of May, 1927, whereas a very long sedimentation period was expected to be necessary for the finely divided clay. Temperature was not the only factor, as higher laboratory temperatures did not bring about this improvement. The treatment is of interest particularly because of the very large volume of water treated.

Coagulation Studies at the Washington Suburban Sanitary District. Robert B. Morse, Carl A. Hechmer, and S. T. Powell. *Industrial and Engineering Chemistry*, vol. 20, No. 1, January, 1928, pp. 56–59. (Abstract by Frank Raab.)

The Washington Suburban Sanitary District receives its water supply from a branch of the Anacostia River. The water is treated at two small rapid sand filter plants, one of which is located in Hyattsville, the other in Burnt Mills. The water has an alkalinity of from 18 to 22 p. p. m. The turbidity, which is subject to sudden changes, ranges from 5 to 5,000 p. p. m. after a rainfall. The water is treated with alum; during periods of high turbiduty soda ash is added to aid in the coagulation. The coagulant is added as the water enters the centrifugal pumps. Lime is added to the filter effluent to bring about a pH of about 8.0. This is necessary to have a pH of 7.0, or a little more, in the distribution system. During high turbidities, when larger doses of alum are required, alum floc passes through the filters, which gives the water in the clear-water reservoir a cloudy appearance.

It was found that small amounts of sodium aluminate used in combination with alum yielded good results. This hastened the alum reaction and secured a better floc, and resulted in a more effective removal of suspended matter and a clearer filter effluent. Less lime yielded the desired pH in the filtered water. Smaller amounts of chlorine produced satisfactory results; while in the end the sodium aluminate treatment proved, likewise, a little cheaper.

Latest Developments in Water Purification. George W. Fuller. Proceedings of Ninth Texas Water Works Short School, January, 1927, pp. 182–186. (Abstract by H. D. Cashmore.)

The newer developments in water purification have not been along the line of new processes but in the modification of the previous methods.

A brief discussion of each of the following developments is given with reference to the towns in which they were tried: (1) Superchlorination and dechlorination; (2) split chlorination and prechlorination; (3) double coagulation; (4) double filtration; (5) water softening; (6) effluent aeration; (7) mechanically cleaned settling basin; (8) new methods in coagulation of water; (9) boiler feed water; (10) new purification plants; (11) experimental studies on filter loading.

The Development of the Hydraulic Jump Mixing Flume for Water Purification. J. W. Ellms. Proceedings Ninth Texas Water Works Short School, January, 1927, pp. 180–182. (Abstract by H. D. Cashmore.)

The development of water purification processes pointed out the fact that thorough mixing of the chemicals with the water was a necessary procedure. The old baffled-mixing chambers and mechanical agitators were found to be faulty in many respects. The need for the proper mixing device was seen.

Experimental work was carried on at Cleveland, Ohio, by the city water department, under the direction of the author, who suggested the use of this procedure. Results of this work led to the following conclusions: (1) It is possible to design a flume in which the phenomenon can be produced; (2) costs of building the flume are about one-third that of the baffled mixing chamber; (3) the flume can be placed at the most suitable place; (4) the loss of head is low; (5) it is an extremely efficient mixing device.

The many installations now being used are ample evidence of the effectiveness of this method of mixing.

Power Gas from Sewage Sludge. Frank C. Vokes and Chas. B. Townsend. *The Surveyor*, vol. 72, No. 1873, December 16, 1927, p. 596. (Abstract by R. E. Thompson.)

Data are given on power production from sludge gas at the sewage works of the Birmingham, Tame, and Rea districts. About 400,000 tons of crude sludge, containing 8 per cent of dry solids, is digested each year. The sludge remains in the primary digestion tanks three months, is then pumped a distance of 4 miles to secondary digestion tanks for a period of two months, and is finally pumped onto drying beds. During digestion about 25 to 33 per cent of the solids is converted into a gas composed of 67 per cent methane, 30 per cent carbon dioxide, and 3 per cent nitrogen, having a calorific value of about 625 B. t. u. per cubic foot. Under the favorable conditions existing, the estimated production cost of current is 0.49d. per unit, effecting a net saving of over $1,000 per annum for the first unit. The estimated cost of gas production on the basis of 16,000,000 cubic feet per annum from this unit is 7½d. per 1,000 cubic feet. The estimated total available output of 10,000,000 horsepower-hours per annum is about 5 times the board's present requirements. Brief details of the reinforced concrete floating gas collector designed for the first unit are included.

Water Pollution Control—Milk Products Wastes. E. F. Eldridge, J. M. Hepler, and H. S. Murphy. Department of Health and Department of Conservation, Michigan, June, 1927. Pamphlet, 15 pages. (Abstract by E. W. Evans.)

This bulletin presents a compilation of several important findings on the treatment and purification of milk products wastes. Investigations conducted in Massachusetts, Wisconsin, New Jersey, New York, Ohio, Iowa, and by the United States Public Health Service are noted, with a brief discussion of the results found.

The experiments conducted at the Michigan State College in cooperation with the State health department are discussed in more detail. Preliminary laboratory experiments indicate that, in using the chemical precipitation method,

a good flow is secured and efficient settling occurs when sufficient quantities of ferrous sulphate and caustic soda are used. At least 0.6 p. p. m. of ferrous sulphate must be used or the precipitate will be red in color. Lime or caustic soda in quantities sufficient to produce a pH of 7.5 to 8.0 will give a good flow with good settling, but produces a large amount of sludge. Broad irrigation of milk products wastes is recommended as a temporary expedient where possible.

LaGrande, Oregon, Sewage Treatment Plant. L. R. Stockman. *Western Construction News*, vol. 3, No. 1, January 10, 1928, pp. 21–24. (Abstract by E. A. Reinke)

This article describes a plant consisting of a 50 by 50 foot Dorr clarifier, twin dosing siphons, and sprinkling filter with 35,000 square feet area. A part of an old septic tank was made over into a separate sludge digester 20 by 80 feet in plan and 15 feet deep, giving slightly less than 1 cubic foot per capita on a population of 15,000. A 3,500-square foot sludge drying bed is provided. Sand for the bed is obtained from the grit chambers, the sewage carrying an abnormally high quantity. The underdrain system of the sprinkling filter contains 76,000 concrete slabs laid over V-troughs in the floor.

An interesting side light on the conditions around the plant was the occurrence of typhoid at one dairy (and among customers of the dairy) using sewage effluent from the old septic tank for irrigation and allowing the cows free access to it. The dairyman brought suit against the city for permanent damages, but was granted only temporary damages because the new plant overcame the possibility of permanent damages.

The Treatment of Sludge. A. P. I. Cotterell. *Journal of the Royal Sanitary Institute*, vol. 48, No. 9, March, 1928, pp. 489–493. (Abstract by W. L. Havens.)

This paper gives a brief description and evaluation of 15 methods for the treatment of sewage sludge. Sludge is defined as residue accruing from the use of grit chambers, screens, and tanks. The methods listed are: (1) Crude sewage applied to land or absorbent; (2) spreading sludge over land; (3) trenching; (4) lagooning; (5) drying on filters; (6) septicization; (7) digestion; (8) yeast fermentation; (9) activation by air; (10) filter pressing; (11) dumping at sea; (12) burning; (13) distillation—experimental only; (14) gas production; (15) use in fertilizers.

Digestion with an end process of drying on filter beds is indicated as a most promising field for successful treatment. Reference is made to the author's "vertical digestion tank" supplemented by two to four months' storage in a series of tanks with reference to gas production; citation is made of installations at Bombay and in Germany and of a commercial project proposed in Australia (Paramatta). This is an excellent paper in brief consideration of the subject.

Work for the Water and Sewage Purification Committee. H. H. King. Report of the King Institute of Preventive Medicine, Guindy, for the year ending March 31, 1927, pp. 10–11. (Abstract by H. D. Cashmore.)

This is a progress report of a portion of the work carried on by the committee on sewage and water purfication. Work in regard to the value of percolating nonsubmerged filters as compared with an ordinary submerged slow sand filter, as well as a comparison of open and closed septic tanks and Imhoff tanks, was carried on.

At the same filtering rate for water the percolating filter gave the best results. At increased head over that used in the submerged filter the same results were obtained except for oxygen absorbed, which was nearly equal. At increased rates for both filters about the same ratio of efficiency was maintained from both a chemical and bacteriological standpoint.

In comparing the work of the sewage tanks it was found that the closed septic tank was better than the open tanks. Insufficient sewage did not allow a comparison of the work for the Imhoff tanks.

The Digestion of Vegetable Wastes and Screenings in Sewage Treatment Plants. W. Rudolfs and H. Heukelekian. **Water Works, vol. 67, No. 3, March,** 1928, pp. 113–116. (Abstract by C. R. Cox.)

Comprehensive researches in the digestion of mixtures of garbage, screenings, fresh sewage solids, and digested sludge were made to ascertain whether garbage could be digested with the sludge at sewage disposal plants. Studies in the digestion of vegetable wastes from canneries will be made in the future. It was found that mixtures of vegetable wastes and fresh sewage solids digested very slowly; that the addition of ripe sludge greatly hastened digestion; and that lime dosing still further hastened digestion. The rate of digestion of vegetable wastes and screenings is slow, owing to the production of acids, which inhibit the growth of putrefactive organisms. The addition of lime neutralizes acidity, the addition of ripe sludge seeds the mixtures, and the addition of fresh sewage solids provides the nitrogenous wastes necessary for normal digestion. It was concluded that vegetable wastes and screenings may be digested in sewage tanks provided the sludge capacity is adequate and provided the ratio of sewage solids to vegetable wastes (nitrogen to carbon) is large. The allowable ratios in practice will be determined by further studies.

The Solution of Oxygen in Sewage. A. S. Parsons and H. Wilson. *The Surveyor*, vol. 72, No. 1869, November 18, 1927, pp. 490–494. (Abstract by C. K. Calvert.)

Experiments were conducted to shed light on the arguments and theories established by the proponents of mechanical aeration. It is claimed that, in the air diffusion method, the film of water about the bubbles may be saturated, but that it follows the bubble to the surface and does not mix with the liquor until the bubble bursts. If this is the case a deep aerator, offering less surface area in proportion to its volume, is less economical than a shallow one.

Two aerators were constructed each 18 inches in diameter. One of them had 6 feet 6 inches and the other 22 feet 6 inches operating depth. Ratio of diffuser area to area of cross section of chamber was 1:9 2. Air was admitted at the same rate to each aerator. Two kinds of liquor were used—(1) sewage and (2) sewage plus activated sludge. The concentration of oxygen increased more rapidly in the plain sewage than with activated sludge, since biologic action is more rapid in the presence of the sludge; but the concentration of oxygen increased in the deep tank as rapidly as or a little more so than in the shallow tank, when like liquors were used in them. The tanks were filled with a mixture of activated sludge and sewage, and air was applied equally as before. The rate of reduction of ammoniacal nitrogen and oxygen demand and the increase of nitric nitrogen were the same in the deep and shallow tanks. However, in aerating to the point of elimination of ammoniacal nitrogen (14 hours) about three times as much air was used in the shallow as in the deep chamber.

The authors conclude that the deep tank is more economical than the shallow one, but point out that in the former more trouble is experienced with sludge floating on account of entrained air. They suggest that the depth of tank should be given attention in its relation to the handling of specific sewages.

Laboratory experiments are reported showing that oxygen concentration is built up very much more rapidly in sewage the pH of which is modified either by the addition of acid or alkali. Sewage pH of 4, 6, 8, and 10, and distilled water at pH 7.6 were found to run near together. The original sewage Hp was 8.0.

DEATHS DURING WEEK ENDED JUNE 9, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended June 9, 1928, and corresponding week of 1927. (From the Weekly Health Index, June 13, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended June 9, 1928	Corresponding week, 1927
Policies in force	71,349,157	67,889,339
Number of death claims	14,477	12,910
Death claims per 1,000 policies in force, annual rate	10.6	9.9

Deaths from all causes in certain large cities of the United States during the week ended June 9, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, June 13, 1928, issued by the Bureau of the Census, Department of Commerce)

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 100 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,627,000. The estimated population of the 94 cities reporting deaths is more than 30,930,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended June 2, 1928, and June 4, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
43 States	1,196	1,648	
100 cities	738	938	805
Measles:			
42 States	15,996	10,628	
100 cities	7,358	2,603	
Poliomyelitis, 43 States	32	28	
Scarlet fever:			
43 States	2,885	3,423	
100 cities	1,250	1,306	1,012
Smallpox:			
43 States	860	721	
100 cities	77	126	99
Typhoid fever:			
43 States	280	498	
100 cities	71	80	58
Deaths reported			
Influenza and pneumonia, 94 cities	975	583	
Smallpox, 94 cities	0	0	

City reports for week ended June 2, 1928

•The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during non-epidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population, July 1, 1926, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported
			Cases, estimated expectancy	Cases reported	Cases reported	Deaths reported

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended June 2, 1928, compared with those for a like period ended June 4, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1928 and 1927, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,657,000 in 1928 and 31,050,000 in 1927. The 95 cities reporting deaths had nearly 30,961,000 estimated population in 1928 and nearly 30,370,000 in 1927. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, April 29 to June 2, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

PLAGUE ON VESSEL

Steamship "Tymeric"—At Barbados, from New Orleans, for Cape Town, Union of South Africa.—On May 21, 1928, the steamship *Tymeric* from New Orleans arrived at Barbados, British West Indies, with a case of suspect plague on board. The case was reported positive May 29, 1928. The *Tymeric* left New Orleans May 11, 1928, arrived May 21 at Barbados, and sailed same date for Cape Town, Algoa Bay, East London, Port Natal, and Lourenço Marquez.

THE FAR EAST

Report for the week ended May 26, 1928.—The following report for the week ended May 26, 1928, was transmitted by the Eastern Bureau of the Health Section of the Secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Aden Protectorate—Aden
Egypt—Alexandria, Suez
India—Bassein, Bombay, Rangoon.

CHOLERA

India—Bassein, Calcutta, Madras
Siam—Bangkok
French Indo-China—Haiphong, Saigon

SMALLPOX

Egypt—Alexandria
Iraq—Basra
India—Bombay, Calcutta, Madras, Moulmein, Negapatam, Rangoon, Vizagapatam
French India—Pondicherry
China—Shanghai, Hong Kong
Japan—Kobe, Osaka, Yokohama
Kwantung—Dairen

Returns for the week ended May 26 were not received from Colombo, Ceylon; Samarinda, Makassar, Belawan-Deli, Padang, nor Tarakan, Dutch East Indies.

ARABIA

Aden—Plague—May 22, 1928—Summary.—On May 22, 1928, a case of plague was reported in the village of Maala, between Crater and Steamer Point, Aden, Arabia. To May 23, 1928, 1,493 cases of plague were reported in Aden, with 1,106 deaths.

CANADA

Provinces—Communicable diseases—Week ended May 26, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from seven Provinces of Canada for the week ended May 26, 1928, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever				1	2			3
Influenza	26			17				43
Poliomyelitis					1			1
Smallpox		1		6	3	3	18	31
Typhoid fever	1		10	7		1		19

Quebec Province—Communicable diseases—Week ended June 2, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended June 2, 1928, as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	2	Scarlet fever	73
Chicken pox	18	Smallpox	19
Diphtheria	44	Tuberculosis	48
German measles	25	Typhoid fever	10
Influenza	5	Whooping cough	5
Measles	135		

CZECHOSLOVAKIA

Communicable diseases—April, 1928.—During the month of April, 1928, communicable diseases were reported in Czechoslovakia as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Anthrax	3		Paratyphoid fever	9	
Cerebrospinal meningitis	16	4	Puerperal fever	48	19
Diphtheria	740	53	Scarlet fever	1,287	23
Dysentery	10	3	Trachoma	262	
Malaria	54		Typhoid fever	365	34

JAPAN

Tokyo, city and district—Dysentery—March 25–April 21, 1928.—During the four weeks March 25 to April 21, 1928, dysentery was reported in Tokyo city and district (Prefecture) as follows: Tokyo city—cases, 95; deaths, 35; Prefecture—cases, 138; deaths, 71. Population—city, 1,995,567; prefecture—2,489,577.

LATVIA

Birth and infant mortality rates, 1925, 1926.—In 1925, 41,314 births were recorded in Latvia, and in 1926, 41,073 births, giving birth rates of 22.4 in 1925 and 21.8 in 1926.

The infant mortality was 107 per thousand births in 1925, and 88 per thousand in 1926.

The population of Latvia, according to the census of 1925, was 1,844,805.

LIBERIA

Monrovia—Quarantine service instituted.—Information has been received under recent date showing the appointment of a sanitary officer to have charge of quarantine service for Liberia, and the establishment of a quarantine station on Bushrod Island, vicinity of Monrovia.

MALTA

Communicable diseases—April, 1928.—During the month of April, 1928, communicable diseases were reported in the Island of Malta as follows:

Disease	Cases	Disease	Cases
Bronchopneumonia	11	Puerperal fever	3
Chicken pox	36	Scarlet fever	5
Diphtheria	2	Trachoma	21
Erysipelas	3	Tuberculosis	27
Influenza	29	Typhoid fever	11
Malaria [1]	1	Undulant (Malta) fever	62
Pneumonia	6	Whooping cough	8
Poliomyelitis	1		

[1] Contracted abroad

Population, civil, estimated 228,575

Mortality.—During April, 1928, 342 deaths were recorded in Malta, of which 14 were caused by tuberculosis.

SENEGAL

Dakar—Conference for Study of Disease Control in West Africa.—During the week ended April 28, 1928, medical representatives from several of the West African colonies, met at Dakar, Senegal, for the purpose of studing the clinical characteristics of West African yellow fever and other diseases, their epidemiology and methods for their prevention and control.

The conference was called by the Governor General of the West African Colonies. The following-named countries were represented at the Conference: French Togoland, Gambia, Gold Coast, Nigeria, and Sierra Leone. The Rockefeller Foundation was represented.

It was resolved that a liaison be formed among the West African colonies; that this liaison operate through a central bureau established for the purpose of collecting and assimilating knowledge relative to the occurrence of infectious diseases in the colonies, or, provisionally, by interchange of visits by members of the medical staff of the several colonies; also, that should any colony report the presence of yellow fever or other infectious disease, the medical departments of all the other countries be privileged to send medical representatives to the infected districts to study the disease and its control.

UNION OF SOUTH AFRICA

Cape Province—Natal—Orange Free State—Typhus fever—April 15–28, 1928.—During the two weeks ended April 28, 1928, typhus fever was reported in the Union of South Africa as follows: Fresh outbreaks in ten districts of the Cape Province, in one district of Natal, and in two districts of the Orange Free State. Two sporadic cases occurred in Europeans.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst. Surg Gen. R C. WILLIAMS, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

VOL. 43 JUNE 29, 1928 NO. 26

A UNIT FOR SCARLET FEVER STREPTOCOCCUS ANTITOXIN[1]

By R. E. DYER, *Surgeon, United States Public Health Service, Assistant Director, Hygienic Laboratory*

During the past few years several methods of testing the potency of scarlet fever streptococcus antitoxin have been tried. Dick and Dick (1) (2) (3), whose work furnishes the basis of the unit here suggested, tested the neutralization of scarlet fever streptococcus toxin by the antitoxin by means of a skin test on human beings; and Wadsworth, Kirkbride, and Wheeler (4) applied this method to the skin of goats. Dochez and Sherman (5) and Blake, Trask, and Lynch (6) (7) measured the antitoxic potency of serums by determining the smallest volume of the antitoxin which, when injected intracutaneously in the area of the rash in an early case of scarlet fever, would produce local blanching (Schultz-Charlton reaction). O'Brien (8) and Okell (9) tested the activity of antitoxins in producing passive immunity in individuals who were susceptible to the toxin of *Streptococcus scarlatinae*, while Parish and Okell (10) compared the potency of antitoxic serums in protecting rabbits against the septicemia produced by inoculation with broth cultures of the scarlet fever streptococcus. Dyer (11), Povitsky (12), Eagles (13) and others have attempted to apply the Ramon flocculation test, which has been employed for testing other antitoxins.

Of the methods cited, those based on testing the potency of antitoxin in neutralizing toxin as shown by skin tests have been used more extensively than any others, and seem to be the most useful. In these methods, as in methods early in use for testing other antitoxins, a fixed amount of a toxin is mixed with different amounts of antitoxin. The amount of toxin used in the mixtures is spoken of as the test dose and, in the case of the scarlet fever streptococcus toxin which we have used, contains five skin test doses—a skin test dose being the amount of toxin necessary to produce a reaction at least 1

[1] EDITORIAL NOTE.—The Permanent Commission on the Standardization of Sera, etc., of the Health Organization of the League of Nations has selected as a basis for study the standard scarlet fever streptococcus serum here described. The report of the commission (Frankfort-on-Main, Apr. 25 to 28, 1928) states:

"Without expressing an opinion on the etiology of scarlet fever or on the methods of testing sera prepared with the products of culture of hemolytic streptococci isolated from cases of scarlet fever, it would be useful to render future researches along this line more readily comparable. To this end, the standard serum adopted by the Federal Government of the United States may be selected as a basis for study, the Hygienic Laboratory has agreed to place at the disposition of the Health Organization of the League of Nations a sufficient quantity of the standard serum."

centimeter in diameter about 24 hours after intracutaneous injection in the majority of individuals susceptible to scarlet fever (1) (14). In using such a method it has been found that a great deal depends on the test subject, due to differences in susceptibility of individuals. In some individuals a certain volume of antitoxin when mixed with a given amount of toxin will show neutralization, while on other subjects several times as much antitoxin may be required to neutralize the same test dose of toxin.

Protocol I illustrates wide variations encountered in attempting to titrate an antitoxin against the toxin.

PROTOCOL I

Illustrating conflicting results obtained in testing the potency of scarlet fever streptococcus antitoxin by the toxin neutralization method without a control serum [1]

Case No.	Toxin [2]	Antitoxin					
	One skin test dose	1/10,000 c. c. [3]	1/10,000 c. c. plus toxin—one skin test dose	1/20,000 c. c. plus toxin—one skin test dose	1/30,000 c. c. plus toxin—one skin test dose	1/40,000 c. c plus toxin—one skin test dose	1/50,000 c. c. plus toxin—one skin test dose
659	+	0	0	0	0	0	0
418	+	0	0	0	0	0	+
519	+	0	0	0	0	+	+
608	+	0	0	0	+	+	+
529	+	0	0	+	+	+	+
555	+	0	+	+	+	+	+

[1] The same toxin and the same antitoxin were used throughout these tests.
[2] Toxin control
[3] Serum control.
0 = Negative reaction.
+ = Positive reaction.

From the foregoing protocol the necessity for some means of eliminating irregularities in results due to the varying susceptibility of subjects is obvious. It would seem that this could be accomplished best by a method similar to that used in the present official standardization of other antitoxins—that is, by the establishing of a standard serum as the fixed basis with which the antitoxins to be tested could be compared. To serve this purpose a serum was selected and dried to insure stability. The redissolved serum was then carefully titrated against the previously selected test dose of toxin on a sufficient number of subjects to determine the reciprocal neutralizing value of the serum and the toxin, one against the other. In applying the standardization test in practice, a range of doses of the standard serum are mixed each with a test dose of toxin and injected intracutaneously. On the same subject, at the same time, a range of doses of the antitoxin to be tested, mixed with the same test dose of toxin, are injected. Thus, the volume of a new antitoxin is determined which will neutralize one test dose of toxin on a given subject, and this volume is compared with the volume of the standard control serum

which also shows neutralization of one test dose of toxin on the same subject at the same time. As the neutralizing value of the standard serum is known, the potency of the new antitoxin may be calculated readily. Thus, if, on a certain individual, 1/400 of a cubic centimeter is found to be the smallest volume of the standard serum which will neutralize one test dose of toxin, and 1/6,000 of a cubic centimeter of a new antitoxin also shows neutralization of one test dose of toxin, then the new antitoxin is 15 times as strong as the standard serum.

It seems desirable that the definition of the potency of scarlet fever streptococcus antitoxin should be expressed in terms of "units" as with other antitoxins in common use. To avoid confusion, possibly arising from different-sized doses of similar products, it also seems desirable that the average therapeutic dose of scarlet fever streptococcus antitoxin should be approximately the same as that of diphtheria antitoxin, the doses of both being expressed in units. It has been found by clinicians that the average therapeutic dose of scarlet fever streptococcus antitoxin should contain enough antitoxin to neutralize from 300,000 to 500,000 skin test doses of toxin. Establishing as a unit 10 times the smallest amount of the standard serum which has been found necessary to neutralize one test dose of toxin, each test dose representing five skin test doses, the therapeutic dose of the antitoxin will approximate in number of units the average dose of diphtheria antitoxin.

The standard scarlet fever streptococcus serum is kept at the Hygienic Laboratory under the same conditions of storage that have been maintained with the standard diphtheria and tetanus unit serums for several years, during which time no measurable deterioration has taken place in the latter serums.

A definite amount of this standard serum is therefore suggested as a permanent unit. This unit has been selected to equal 10 times the smallest amount of scarlet fever streptococcus antitoxin necessary to neutralize one test dose of toxin, but the designated amount of serum, and not the toxin dose, is the final measurement of reference; that is, the unit will remain the same without regard to the dose of toxin used from time to time for comparing the standard with other antitoxins, or the method of test employed. The standard serum as dissolved at present contains 40 such units per cubic centimeter.

Protocol II illustrates the results of tests to determine the toxin neutralizing potency of a new antitoxin in comparison with the standard serum.

PROTOCOL II

Potency test on scarlet fever streptococcus antitoxin Lot X

[1] Standard serum containing 40 units per c. c.
[2] Serum control.
[3] Toxin control.

0=No reaction.
NOTE.—Measurements of two diameters of each reaction are recorded in millimeters.

The fraction of a cubic centimeter of serum is stated in each instance. Reactions less than 1 centimeter in diameter are considered negative. Neutralization is considered complete only when reactions to toxin-antitoxin mixtures are negative at both the 24 and 48 hour readings.

Protocol III illustrates the titration of a new lot of antitoxin by a manufacturer, while Protocol IV gives the results of tests made at the Hygienic Laboratory on the same lot.

PROTOCOL III

Manufacturer's protocol giving the results of his tests to determine potency of a new lot of antitoxin

CURRENT WORLD PREVALENCE OF COMMUNICABLE DISEASES [1]

United States, May 6–June 2, 1928

The mortality rate from all causes in 67 large cities in the United States dropped off rapidly after the second week in May from the high level which had prevailed since the middle of March. Nevertheless, the general death rate in these cities remained relatively high; for the week ended June 2 it was 13.3 per 1,000 population (annual basis), as against 11.8 in the corresponding week of 1927 and 12.3 in the corresponding week of 1926. Although the death rate at no time rose sharply to an epidemic height, the maximum rate for a single week being 15.5 in the week ended May 5, the mortality rate averaged approximately 15 per 1,000 for a period of 8 weeks, and the death rate in these cities from January 1 to June 2 has been 14.3 as against 13.5 in the corresponding period of 1927. The rate is more favorable to date for the year, however, than it was in 1926, when there was a marked respiratory epidemic, and is about the same as it was in 1925.

Influenza and pneumonia.—The mortality from influenza and pneumonia in the principal cities also remained on a relatively high level as compared with the preceding year, but in the week ended May 19 the deaths from these causes turned downward. The death rate from influenza and pneumonia combined in the week ended May 19 was higher, on the average, than last year in the cities in all sections of the country except in the South Atlantic, West South Central, and Pacific divisions.

The number of cases of influenza reported by 31 States declined sharply, however, during the month of May. The maximum was reported for the week ended May 5, with 4,185 cases, and the weekly incidence dropped to 1,212 for the week ended June 2. The reported incidence in the early winter showed only a normal seasonal increase and compared very favorably with the same period of 1927; but in 1927 the maximum incidence was passed in the early part of March, when 2,532 cases were reported for the week ended March 10, whereas in the current year the most marked increase in cases occurred unusually late. This may have some relation to the fact that no real epidemic prevalence, such as occurred in February and March, 1926, took place, although cases of the disease were numerous throughout April. The decline in cases during May was noted in practically all States.

Meningococcus meningitis.—A decrease in the reported incidence of meningococcus meningitis occurred in the week ended June 2, when 101 cases were reported by 42 States, which is the smallest number reported by these States since the week ended March 3. During the four weeks ended June 2, these 42 States reported 493 cases, of

---

[1] From the Office of Statistical Investigations, United States Public Health Service.

which 359 were in the following eight States: California, Illinois, Michigan, Missouri, New Jersey, New York, Pennsylvania, and Wisconsin. Of these eight States, only New York showed a decline from the total cases reported in the preceding four-week period, and Michigan, Missouri, New Jersey, and Wisconsin reported an increased number.

Smallpox.—The incidence of smallpox continued to decline during the month of May, the total number of cases reported by 42 States during the four-week period ended June 2 being 3,519, as compared with 3,900 for the preceding four-week period. The decline has been general, with no very marked change in the number of cases in any State. A slight increase in the number of cases was reported in Alabama, where the cases for the two weeks ended June 2 numbered 58, as compared with 15 in the preceding two weeks.

Scarlet fever.—The number of cases of scarlet fever reported weekly by 42 States and the District of Columbia has declined steadily though slowly since March. In the week ended June 2, the total number reported was 2,762 cases, as compared with 4,022 in the week ended May 5. The decline may be expected to continue throughout the summer, as the lowest incidence is usually reached at the end of August. The total reported incidence has been somewhat less in the current year than in 1927, but about equal to that in 1926. The case incidence reported in cities, however, indicates that the disease has been more prevalent than a year ago in the South Atlantic, East South Central, and West South Central divisions of the country, but much less prevalent in all other sections.

Diphtheria.—A gradual decline in the incidence of diphtheria continued through May and there were about 900 cases reported by 42 States for the week ended June 2, approximately 200 less than the weekly totals in the first half of May. During the four-week period ended June 2, 3,951 cases were reported, which was 1,000 less than the number reported for the same period in 1927, but only slightly less than in 1926. Throughout April and May the number of cases reported by the individual States showed very little change. In May a slight increase occurred in California, New Jersey, and Michigan, but the general trend in nearly all States was downward.

Typhoid fever.—The number of cases of typhoid fever reported weekly by 42 States began to increase during the month of May. For the four-week period ended June 2, there were 873 cases reported, as compared with 687 cases for the preceding four-week period. A slight increase occurred in several of the States. In Alabama the number of cases increased from 17 in the four-week period ended May 5 to 36 in the four-week period ended June 2; in California the number increased from 20 to 62; in Georgia from 13 to 53; in Tennessee from 16 to 39; in Wisconsin from 11 to 126. The increase in typhoid fever cases is normal for this season of the year, and the incidence is considerably lower than that of last year and slightly less than in 1926.

Poliomyelitis.—The number of cases of poliomyelitis increased during May; 102 cases were reported by 43 States during the four weeks ended June 5, as compared with 81 the preceding four weeks. In California the number of cases declined from 23 to 18, but in New York the number increased from 4 to 13; in Massachusetts, cases increased from 3 to 7; and in Pennsylvania 5 cases were reported in the earlier four weeks and 6 cases in the later. No other States reported more than five cases in either period.

Measles.—The expected seasonal decline in the incidence of measles began during May, as is evident from the reports of 38 States, which showed a total of 32,000 cases for the two weeks ended June 2, as compared with 36,500 cases for the two-week period ended May 5. In general, measles has maintained a higher level throughout the present year than in 1927, but is lower than in 1926. Among the States showing a significant decrease in the number of cases of measles reported are Arkansas, Georgia, Indiana, Louisiana, Maryland, Massachusetts, North Carolina, and Tennessee. On the other hand, several of the States reported a slight increase in the number of cases for the same period. In New York the number of cases reported increased from 7,012 in the two weeks ended May 5 to 8,157 in the two weeks ended June 2, and in Pennsylvania, from 4,689 to 5,548. The decrease should become more general during June, as the incidence reaches its lowest point in midsummer.

Foreign Countries[1]

The general prevalence for certain epidemic diseases in most foreign countries during March and April is summarized below.

Plague.—The plague outbreak at Aden decreased rapidly in April; 314 cases were reported in the two weeks ending April 7, 167 cases were reported in the next two weeks, and only 66 cases in the two weeks ending May 5. The reported fatality of cases has averaged about 75 per cent, and the deaths since the beginning of the year give a death rate of no less than 20 per 1,000 population. The population of Aden is about 55,000.

At Baghdad sporadic cases continued to occur, but only 18 cases had been reported from January 1 to May 12, 1928.

In India, plague was very much more in evidence in the United Provinces in March than elsewhere. During the four weeks ended March 24 14,875 deaths were attributed to plague in that Province, being 73.5 per cent of all India's plague mortality during those weeks. There were two main centers—an eastern one, including the districts of Azamgarh, Ghazipur, Gorakhpur, Bastia, and Fyzabad, and a northwestern one, in which the districts of Muzaffarnagar, Moradabad, Badaun, Bareilly, Pilibhit, Shahjahanpur, and Hardoi reported the largest number of cases.

---

[1] Data from the Monthly Epidemiological Report of the Health Section of the League of Nations' Secretariat, May 15, 1928, supplemented by information published in the PUBLIC HEALTH REPORTS.

The maximum plague mortality in the eastern center of the United Provinces is normally reached in March, so no further considerable increase is likely to occur. In the western center, however, the peak of the curve is not likely to be reached before the middle of April. The present outbreak, in so far as the United Provinces is concerned, is likely to reach the same intensity as that of 1923; it is considerably more severe than those which occurred between 1924 and 1927.

The plague situation remains very favorable in the Punjab, only Ambala and neighboring districts in the northern part of the Province being affected by the disease.

At Hong Kong, one case of plague was reported on May 4, the first since September, 1923.

At Suez, 8 cases of plague occurred during April, and 42 cases had been reported since the beginning of the year. One case of plague was reported from Algiers on May 2, the only case to occur in the current year. No cases were reported in April in Mediterranean countries.

The number of plague cases reported in Senegal increased as usual in April, and during the first 20 days of that month 51 cases were reported in the district of Tivaouane and 30 cases in that of Thies. No plague case has been reported at Dakar since November. There were 12 plague cases at Lagos during the four weeks ended April 28, but none elsewhere in Nigeria; no case has been reported at Ijebu since February 11.

Plague was reported in several localities in Brazil during the early months of the year. In January there was a small outbreak at Parnahyba in the State of Sao Paulo; in March there were 2 cases at Porto Alegre. Thirty cases were reported at Bahia and 12 at Rio de Janeiro during the first quarter of the year. The Federal Health Service stated on April 19 that the last cases in those towns occurred 20 and 30 days previously, respectively.

In the Argentine, sporadic plague cases have been reported since the beginning of the year at Rosario, Buenos Aires, and at various inland localities in the Provinces of Cordoba, Santa Fe, and Santiago, which comprise the great plains west of the Parana River.

In Peru, 71 plague cases were reported in January and 41 in February, which is more than were reported last year but less than were reported in earlier years; 8 of these cases occurred in the town of Lima. Only 10 cases were reported at Guayaquil during the two first months of the year, as compared with 52 and 56 cases during the corresponding periods of 1926 and 1927, respectively.

Plague was reported in March about 60 miles from Caracas, in the State of Miranda in Venezuela.

Cholera.—The number of cholera cases reported in India increased from 9,293 during the three weeks ended March 3 to 14,144 in the following three weeks. This is the season, however, when such an increase usually occurs. A large majority of the cases (81 per cent) occurred in Bengal and the adjoining districts of Bihar and Orissa; the increase was confined to this area, whereas the incidence has decreased in Madras Presidency since the beginning of February.

In Siam, 768 cholera cases were reported during the first quarter of 1928, which is slightly more than the number reported during the corresponding period of the preceding year. There has been no increase of the incidence since early in February.

Cholera cases have increased steadily during the current year in Cochin-China, where 593 cases were reported in the first 20 days of April as against 462 in the preceding 20 days. In Cambodia, the number of cases began to increase at the end of March, and 145 cases were reported in the first 20 days of April, as compared with 55 cases in the first 20 days of March. The disease is more prevalent than it was last year in Cochin-China, but less prevalent in Cambodia. Very few cases have been reported in other parts of Indo-China.

Influenza.—No epidemics of influenza occurred during the first four months of the year anywhere in Europe, and the past winter can be described as one of the most favorable influenza years since 1918. In English towns, the mortality from influenza during the first four months was equally low only in 1921 and 1923.

There was a small increase of influenza deaths at the end of March in English, Dutch, and German towns, but the incidence soon decreased again. In Vienna, where influenza was little in evidence during the preceding winter, it caused 50 deaths in March, as compared with 6 in February.

In the Netherlands, the number of deaths attributed to influenza increased from 122 in February to 419 in March, giving a total of 688 deaths during the first quarter of 1928, as compared with 2,824 and 432 deaths during the corresponding period of 1927 and 1926, respectively. In March, 73 deaths occurred at Rotterdam, 32 at The Hague, and 22 at Amsterdam.

In the Union of Soviet Socialist Republics, influenza was more prevalent in January, the latest month for which figures are available, than in the corresponding month a year ago. Moscow town and Government reported 63,481 cases and Leningrad town and Government 10,931 cases, as compared with 16,486 and 2,163 cases, respectively, in January, 1927. During the same month, there were only 63 deaths from influenza in Leningrad and 46 in Moscow, which shows that the disease was of a benign type. The increase over last year seems to have extended over the whole country, but to have been least marked in Siberia.

Influenza was reported to be epidemic and causing a considerable mortality in December, 1927, in the Province of Chihli in Northern China; in November it had been epidemic in Shantung and Kiangsu, the two Provinces south of Chihli. Influenza was epidemic in December also in Yunnan, but was of a mild type, causing no appreciable mortality.

There was a slight increase of deaths attributed to influenza in towns in Japan in March, the number being 450 during the four weeks ended March 31, as compared with 228 during the preceding four weeks.

CURRENT STATE MORTALITY STATISTICS

For the information of public health officials and others interested, the data in the following tables have been compiled from the monthly mortality reports of State health departments for the latest month for which published records are available. Statistics of most communicable diseases are not included, since they are available in other tabulations in the Public Health Reports. Statistics of deaths from other causes are limited for the most part to those causes which appear in the State reports. In the case of States which publish detailed mortality reports each month, the record of only the principal groups of causes and certain important specific causes have been used.

For purposes of comparison, the mortality records for a few preceding years are given, the rates being for the month corresponding to the last month for which the 1928 rate is available.

These tabulations will be enlarged as the current data on mortality from additional States become available.

COURT DECISION RELATING TO PUBLIC HEALTH

Issuance of permit for conduct and maintenance of stable.—(California First District Court of Appeal, Division 2; Ryan *v.* Andriano et al., 266 P. 831; decided April 19, 1928.) The plaintiff operated a stable under a permit issued in the name of the person from whom he had purchased the stable. On application to the board of supervisors of the city of San Francisco for permission to make additional improvements, it was noticed that the permit was not in the plaintiff's name, and he was instructed first to procure such a permit. Application for a permit was made, but protests against the granting of the same were received by the board, and finally, after two years,

the application was denied. During the pendency of the application the board did not specify objectionable features of the stable and did not fix a time within which the plaintiff was required to remove same. The stable ordinance of the city required a permit for the maintenance of a stable, and also contained the following provisions:

SEC. 4. The board of supervisors shall not refuse a permit for the maintenance of a stable in a building now constructed and maintained as a stable except upon satisfactory evidence that such stable is conducted in an insanitary manner and the failure to remove the objection to the manner of its maintenance within a time to be prescribed by the board of supervisors.

SEC. 6. No permit shall be refused or revoked by the board of supervisors except after a full hearing, and then only in the exercise of a sound and reasonable discretion by said board.

The plaintiff's stable was in operation when the said ordinance was passed. Upon the board's denial of his application, the plaintiff sought by mandamus to compel the granting of a permit. The appellate court reversed the lower court's judgment denying a writ of mandamus, and held that the plaintiff's application for a stable permit could not be denied without opportunity being first given him to remove objections to be specified by the board within a time to be also specified by the board, as provided in section 4 of the ordinance.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Tests with the Activated Sludge Method of Sewage Treatment at Waldenburg (Silesia). G. Jordan Gesundh. Ign. 51, 150-6 (1928). (Abstract by Wayne L. Denman in *Chemical Abstracts*, vol. 22, No. 9, May 10, 1928, p. 1641.)

"The purification plant used in this work consists essentially of a concrete basin which is alternately divided by baffles. Circulation of the sewage is accomplished by means of paddle wheels. The plant handles a mixture of domestic and industrial sewage. The industrial sewage amounts to about 8 per cent of the domestic sewage. Three series of tests were made to determine the normal and high rates of treatment. These rates were 2, 1.5, and 1.1 per second. At 1.1 per second a good sludge is obtained It is in large clumps and its volume is reduced to 25 per cent in 15 minutes. Its water content is 98.5 per cent. At 2 per second very poor results were obtained. The sludge was of a fine structure, and in 15 minutes its volume was 80-90 per cent, with a water content of 99 5 per cent. At a rate of 1.5 per second better results were obtained but were not up to those obtained at 1.1 per second. The effect of suspended matter such as finely powdered coal was tried and found to be very harmful, but the trouble vanishes as soon as the sewage clears. The addition of a substance such as $Al_2(SO_4)_3$ will overcome this difficulty. The action of phenol was noted, as the industrial sewage contained a small quantity from coke plants. It was found that phenol present in considerable amounts did little if any harm. The effluent was clear and had a slight earthy odor. Sewage consisting of 10 per cent phenol sewage (13 days at 457 p. p. m. phenol and 21 days at 191 p. p. m. phenol) may be satisfactorily treated by the activated sludge process. A very high bacterial removal is obtained. For a plant of this type exact and rigorous attention to details must be observed if the operation is to be successful."

Seeding New Tanks. Willem Rudolfs. Report of the Department of Sewage Disposal of the New Jersey Agriculture Experiment Station for year ending June 30, 1927, pp. 284–294. (Abstract by W. L. Havens.)

The difficulty sometimes experienced in starting the operation of a new tank was deemed of sufficient importance to warrant laboratory experiments in order to determine what could be substituted for ripe sludge when the latter was not available. Definite quantities of fresh solids were mixed with ripe sludge, horse manure, cow manure, and muck from a creek and results compared with fresh solids seeded with ripe Imhoff sludge. It was found that neither manure nor muck is as effective for seeding as ripe sludge. Muck was about half as good as ripe sludge and horse and cow manure still less. If sludge from a polluted stream is available for seeding, it is to be favored. Seeding with horse manure and additions of lime are beneficial, but still inferior to seeding with ripe sludge. Additions of lime to fresh solids when ripe sludge is present for seeding keeps floating solids down.

Sanitary Districts in Missouri. Anon. *The American City*, vol. 38, No. 4, April 1928, p. 125. (Abstract by J. B. Harrington.)

In March, 1927, the State law of Missouri was reframed to provide for the construction of sanitary sewers in all suburban districts of any county having a population of over 75,000 people. The procedure to be followed requires that a petition signed by 100 property owners must be submitted to the circuit court. The circuit judge, upon favorable decision, appoints three supervisors, who organize and appoint a secretary, an attorney, and an engineer, and levy a tax not to exceed 10 cents per 100 square feet of area for preliminary work.

Studies on the Decomposition of Cellulose. H. Heukelekian. Report of the Department of Sewage Disposal of the New Jersey Agricultural Experiment Station for year ending June 30, 1927, pp. 272–284. (Abstract by W. L. Havens.)

Experiments were carried on during the past year in an effort to study the fundamental processes of sludge digestion, not from the standpoint of changes in bacterial life, but as measured by the decomposition of organic material. Two methods were employed--first, following the changes in the cellulose content of digesting material, and, second, adding cellulosic substance to ripe sludge and following the changes induced. The following conclusions were reached as a result of these experiments: (1) The native cellulose of fresh solids as well as cellulose added to ripe sludge in the form of filter paper decomposes rapidly; (2) the decomposition of cellulose takes place in the early part of the digestion, namely, the first three weeks; (3) the decomposition of cellulose gives rise to acidity, which retards the general course of the digestion; (4) cellulose decomposition takes place under acid conditions, but the addition of lime accelerates the rate of decomposition; (5) the decomposition of cellulose is accompanied by the production of gas, the volume of which is much smaller than that produced in the decomposition of an equal amount of mixed organic matter in fresh solids; (6) there is a lag of 5 or 6 days before the decomposition of cellulose starts; (7) the rapidity of decomposition of cellulosic substances is correlated with their cellulose content; (8) cellulose content of the solids collected from the inlet end of an Imhoff tank is higher than that from the outlet end; (9) the digestion of the material from the inlet end was similar to the type of digestion obtained from the mixture of solids. The material from the outlet end had a shorter period of acid digestion, lower acidity, and a higher alkalinity and higher ash content than the material from the inlet end.

Design and Operation of Storm Tanks. C. Chamberlain. *The Canadian Engineer*, vol. 54, No. 1, January 3, 1928, pp. 101–103. (Abstract by R. E. Thompson.)

The storm water at the York Township plant flows into a small creek, and it was therefore considered necessary to provide for more than the usual "three times the dry weather flow." As this condition was expected to last for only a few years, two tanks, 77 feet square, with sloping bottoms and equipped with Dorr scrapers, were constructed which could be used without alteration for treatment of domestic sewage in the future. The material collected is of two types—(1) coarse material such as stones, cinders, and brick fragments; and (2) material varying from fine sand to mud, containing a certain amount of organic matter. The former material interfered with the operation of the diaphragm pump used for removing the sludge, and the plant has now been rearranged somewhat to provide an extra grit chamber for removal of this coarse material. The fine material is removed from the tanks with a Stereophagus pump and deposited in sand beds. After being dried, it is utilized for fill around the beds. The streets are unpaved and a great deal of material is carried into the sewers during storm periods. Following one storm of 2½ hours' duration, 175 cubic yards of material was removed from the tank and 10 cubic yards from the additional grit chambers.

Returned Sludge in Water Purification. A. W. Bull. *Water Works*, vol. 67, No. 3, March, 1928, p. 112. (Abstract by C. R. Cox.)

This is a summary of experiments made at Columbus and Pittsburgh to ascertain the effect of adding settled sludge to water dosed with lime and soda ash, such as is the practice at Benton Harbor, Mich., Piqua, Ohio, and Hinsdale and Springfield, Ill. Results indicate that the addition of sludge increases the speed of the softening reaction to a marked extent, although the hardness could not be reduced much below 100 p. p. m. by even larger amounts of added sludge. Thus, 19 hours' agitation of the treated water was necessary to produce the same softening reaction secured by 2 hours' agitation with the same chemical doses plus 50 c. c. of sludge per gallon, or by 1 hours' agitation with 100 c. c. of sludge. Best results were secured at Columbus with initial concentrations of 15,000 p. p. m. suspended solids, whereas at Pittsburgh 7,100 p. p. m. was the best initial concentration. The beneficial results "are due to either a catalytic speeding up of the reaction or, more probably, to a reduction in supersaturation." Settled sludge may be easily returned to raw water through the use of continuously cleaned sedimentation basins, such as the Dorr clarifier.

Reservoir Protection. Carl Wilson. *Water Works*, vol. 67, No. 2, February, 1928, p. 50. (Abstract by H. B. Hommon.)

Storage reservoirs: There are no communities on the tributary watersheds; and for control over pollution from landowners and other sources the city enforces the State laws regarding pollution of domestic waters. All reservoirs are fenced and patrolled, and hunting, fishing, boating, bathing, and picnicking are prohibited inside the fenced areas. Grazing is prohibited within half a mile of the reservoirs, and leaching cesspools and earth privies are not permitted closer than 250 feet.

Distribution reservoirs: These reservoirs are protected by (1) strong wire fencing that practically excludes the public; (2) resident patrolmen; (3) bypassing storm water and carrying domestic sewage outside the drainage basins; (4) prohibiting leaching cesspools and privy vaults on the land draining to the reservoirs; and (5) requiring that domestic animals, including chickens, be kept 100 feet away from the water.

Chlorination: All water is chlorinated as it leaves the distribution reservoirs. No other purification is considered necessary.

Abolition of Cross Connections Causes Lively Discussion. Anon. *Engineering News-Record*, vol. 100, No. 12, March 22, 1928, pp. 488–490. (Abstract by C. R. Cox.)

A special committee of the New England Water Works Association reported upon cross connections at the March 14, 1928, meeting. The report was in the nature of a compromise in which the details of the problems involved were discussed in a report of 45 pages, including 25 pages of appendices.

Subcommittee No. 1 on fire hazards recorded 12 cases where fires broke out simultaneously with the interruption of the public water supplies. This committee emphasizes the fact that the New York State labor law permits double the number of employees in buildings equipped with sprinkling systems supplied from two individual sources. The committee concluded that secondary supplies of sufficient capacity were impracticable in cost unless ponds or rivers were utilized and that cross connections should be used to combine the two supplies for common fire-protection systems.

Subcommittee No. 2 on health hazards cited 22 epidemics due to cross connections containing a single gate or check valve. The committee reviewed the position of the public health authorities by stating that, although it was necessary seriously to consider economical phases of fire losses, the saving of life rather than money must be the predominant consideration. This committee stated that the courts had placed responsibilities upon the municipalities for water-borne epidemics when such are due to a negligence in design, installation, operation, or inspections of cross connections. The responsibility also rests upon State authorities, although such responsibility is moral rather than legal.

The committee, therefore, compared the relative fire and health hazards by weighing the economic losses resulting from the 12 fires mentioned above in contrast to the intangible as well as economic losses of 8,028 cases of typhoid fever with 26 deaths and more than 1,000 cases of enteric disturbances occurring with losses by death and disability running into the millions of dollars. They therefore concluded that cross connections with single check valves were too hazardous and that even the best installations of double check valves may fail from lack of inspection. Statistics are given regarding the frequency that leaky valves were found during tests at New Bedford, Mass., and in Connecticut.

In general the committee feels that double check valves of the latest improved type, properly installed and adequately safeguarded, furnish the best protection of any device now known. It is hoped that recent installations of these valves will provide data upon the actual effectiveness of these devices. The committee feels that State regulations should be promulgated, but that our responsibility should rest upon the municipalities wherein cross connections are maintained. The report recommends cooperative inspection of double check valves by municipal and State authorities and by the owners and the insurance companies at quarterly intervals.

The final resolutions recommended by the committee were not adopted by the association, pending the printing of the full report in the June issue of the *Journal* of the association and a detailed study of the report by the members.

DEATHS DURING WEEK ENDED JUNE 16, 1928

Summary of information received by telegraph from industrial insurance companies for the week ended June 16, 1928, and corresponding week of 1927. (From the Weekly Health Index, June 20, 1928, issued by the Bureau of the Census, Department of Commerce)

	Week ended June 16, 1928	Corresponding week, 1927
Policies in force	65, 735, 862	62, 918, 546
Number of death claims	12, 187	11, 891
Death claims per 1,000 policies in force, annual rate	9. 7	9. 9

Deaths from all causes in certain large cities of the United States during the week ended June 16, 1928, infant mortality, annual death rate, and comparison with corresponding week of 1927. (From the Weekly Health Index, June 20, 1928, issued by the Bureau of the Census, Department of Commerce)

Undulant (Malta) fever:	
Iowa	2
Minnesota	1
Vincent's angina:	
Maryland	13
Whooping cough:	
Iowa	39
Maryland	265
Minnesota	297
Ohio	548

RECIPROCAL NOTIFICATIONS

Notifications regarding communicable diseases sent during the month of May, 1928, by departments of health of certain States to other State health departments

Disease	California	Illinois	Minnesota	New Hampshire	New Jersey	New Mexico	New York	Washington
Diphtheria		2						
Dysentery (amebic)			1					
Encephalitis (epidemic)			1					
Measles							1	
Scarlet fever							3	
Smallpox	1	4		1	1			1
Tuberculosis	2		50					
Typhoid fever						1		
Undulant (Malta) fever			1					

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 98 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,560,000. The estimated population of the 93 cities reporting deaths is more than 30,900,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended June 9, 1928, and June 11, 1927

	1928	1927	Estimated expectancy
Cases reported			
Diphtheria:			
43 States	1,337	1,520	
98 cities	808	959	791
Measles:			
42 States	13,859	9,192	
98 cities	6,191	2,529	
Poliomyelitis:			
43 States	30	30	
Scarlet fever:			
43 States	2,682	3,078	
98 cities	1,193	1,426	902
Smallpox:			
43 States	683	631	
98 cities	66	120	89
Typhoid fever:			
43 States	313	609	
98 cities	55	65	70
Deaths reported			
Influenza and pneumonia:			
93 cities	848	577	
Smallpox:			
93 cities	0	0	

City reports for week ended June 9, 1928

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible but no year earlier than 1919 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[1] Dengue: 1 case at Charleston, S. C.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended June 9, 1928, compared with those for a like period ended June 11, 1927. The population figures used in computing the rates are approximate estimates as of July 1, 1928 and 1927, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had estimated aggregate populations of approximately 31,657,000 in 1928 and 31,050,000 in 1927. The 95 cities reporting deaths had nearly 30,961,000 estimated population in 1928 and nearly 30,370,000 in 1927. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, May 6 to June 9, 1928—Annual rates per 100,000 population compared with rates for the corresponding period of 1927 [1]

FOREIGN AND INSULAR

THE FAR EAST

Report for the week ended June 2, 1928.—The following report for the week ended June 2, 1928, was transmitted by the Eastern Bureau of the Health Section of the Secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Plague, cholera, or smallpox was reported present in the following ports:

PLAGUE

Ceylon.—Colombo.
India.—Bassein, Bombay, Rangoon.
China.—Amoy.

CHOLERA

India.—Bassein, Calcutta, Madras, Moulmein, Rangoon.
Siam.—Bangkok.
French Indo-China.—Haiphong, Saigon.
China.—Canton.

SMALLPOX

India.—Bombay, Calcutta, Madras, Rangoon.
French India.—Pondicherry.
Dutch East Indies.—Bolawan-Deli.
China.—Shanghai, Hong Kong.
Japan.—Kobe.
Kwantung.—Dairen, Port Arthur.
Manchuria.—Changchun, Mukden.
Korea.—Fusan.

BRAZIL

Bahia—Interior of Province—Yellow fever.—Under date of June 20, 1928, three cases of yellow fever were reported at Bahia, with spread of the disease in the interior. Two of the reported cases at Bahia were stated to be mild.

CANADA

Provinces—Communicable diseases—Week ended June 2, 1928.—The Canadian Ministry of Health reports cases of certain communicable diseases from five Provinces of Canada for the week ended June 2, 1928, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Alberta	Total
Cerebrospinal fever			2	3		5
Influenza	15			9		24
Lethargic encephalitis				2		2
Poliomyelitis				1		1
Smallpox			19	8	1	28
Typhoid fever			10	9		19

Quebec—Communicable diseases—Week ended June 9, 1928.—The Bureau of Health of the Province of Quebec reports cases of certain communicable diseases for the week ended June 9, 1928, as follows:

Disease	Cases	Disease	Cases
Chicken pox	17	Scarlet fever	85
Diphtheria	35	Smallpox	21
German measles	7	Tuberculosis	2
Influenza	4	Typhoid fever	12
Measles	136	Whooping cough	6

Vital statistics—April, 1928.—Births and deaths in the Province of Quebec for the month of April, 1928, were reported as follows:

Estimated population	2,650,400
Births	6,635
Birth rate per 1,000 population	30.5
Deaths	2,984
Death rate per 1,000 population	13.7
Deaths under 1 year	886
Infant mortality rate	133.5
Deaths from—	
Cancer	125
Cerebrospinal meningitis	5
Diabetes	22
Diarrhea	112
Diphtheria	27
Heart disease	248
Influenza	100
Measles	40
Pneumonia	371
Poliomyelitis	2
Scarlet fever	17
Smallpox	0
Syphilis	5
Tuberculosis (pulmonary)	279
Tuberculosis (all other forms)	55
Typhoid fever	16
Violence	67
Whooping cough	30

GREAT BRITAIN

England and Wales—Vital statistics—January to March, 1928.—During the first quarter of the year 1928, 168,099 births and 136,315 deaths were registered in England and Wales, giving a birth rate on an annual basis, of 17.4 per 1,000 population and a death rate of 14.1 per 1,000. The infant mortality was 80 per 1,000 births.

During the 13 weeks ended March 31, 1928, communicable diseases were notified in England and Wales as follows:

Disease	Cases	Disease	Cases
Diphtheria	18,433	Puerperal pyrexia	1,526
Ophthalmia neonatorum	1,437	Scarlet fever	23,411
Pneumonia	22,296	Smallpox	4,730
Puerperal fever	630	Typhoid fever	622

Scotland—Vital statistics—January to March, 1928.—The Registrar-General of Scotland has published statistics for the first quarter of 1928 which show that the birth rate for Scotland for that quarter was 19.9 per 1,000 population, the death rate 15.9 per 1,000, and the deaths of infants under 1 year of age was 107 per 1,000 births.

The following items are taken from quarterly returns of births, deaths, and marriages registered in Scotland during the quarter ended March 31, 1928:

Births	24,246
Marriages	7,382
Deaths (total)	19,385
Deaths under 1 year	2,594
Deaths from—	
Bronchitis	1,290
Bronchopneumonia	1,017
Cancer	1,736
Cerebrospinal meningitis	42
Diabetes	133
Diarrhea and enteritis (under 2 years)	145
Diphtheria	191
Dysentery	2
Heart disease	2,397
Influenza—	
Sole cause	81
With other causes	350
Lethargic encephalitis	24
Malaria	2
Measles	558
Nephritis (acute)	59
Nephritis (chronic)	485
Paratyphoid fever	6
Pneumonia	1,030
Poliomyelitis	0
Puerperal sepsis	72
Scarlet fever	47
Syphilis	29
Tetanus	2
Tuberculosis (pulmonary)	848
Tuberculosis (all other forms)	391
Typhoid fever	12
Whooping cough	361

GREECE

Corfu—Plague—June 20, 1928.—Under date of June 20, 1928, 15 cases of plague with 3 deaths were reported at Corfu, Greece.

NOVA SCOTIA

Halifax—Communicable diseases—1926-27.—The report of the City Health Department of Halifax, Nova Scotia, for the year ended April 30, 1928, shows a decided decrease in the prevalence of communicable diseases as compared with the preceding year.

The numbers of reported cases of certain communicable diseases in Halifax for the years ended April 30, 1927, and April 30, 1928, are shown in the table below:

Disease	1926-27	1927-28	Disease	1926-27	1927-28
Cancer	4	1	Poliomyelitis	1	2
Cerebrospinal meningitis	1	2	Scarlet fever	193	162
Chicken pox	9	13	Smallpox	0	2
Diphtheria	123	84	Tuberculosis	20	17
Erysipelas	1		Typhoid fever	1	6
Measles	296	20	Whooping cough	100	4
Paratyphoid fever		2			

VENEZUELA

Births and deaths, 1922-1926.—The following table gives the numbers of births and deaths in Venezuela for the years 1922 to 1926, inclusive. The population of Venezuela is given as 2,490,604 in 1923 and 3,026,878 in 1926.

Year	Births	Deaths	Year	Births	Deaths
1922	76,385	56,498	1925	95,741	51,782
1923	82,137	54,509	1926	91,648	60,002
1924	81,750	54,261			

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following tables must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given.
